© 2016 Masaryk University
The educational material Rollpilates is geared to all students of Masaryk University who attend PE classes at the University Sports Centre, the Faculty of Sports Studies (primarily to those attending the courses p9905 and p9904 Physical Education - Rollpilates). For students studying at the Faculty of Sports Studies, the material can serve as a manual in their teaching practice. It can also be used by lecturers and teachers who do not teach or lecture at the faculty; it can be used by everybody who is interested in or lectures Pilates or any Body and Mind exercise. It is geared to the sporting public too. The material focuses on Pilates exercise with foam rollers, which is supported by fascia-oriented exercise, quite a new type of exercise in the field of sport. The material includes the theory and principles of Pilates and fascia-oriented exercise and the battery of exercises, where Pilates with foam rollers and fascia-oriented exercises are depicted, described and explained. The material is available for mobile devices (epub version).

About project

The team of three lecturers from the University Sports Centre at the Faculty of Sports Studies, Masaryk University are the authors the project aiming to open and introduce a new sports course named Rollpilates. The course introduces the involvement of the sports aid called “roller” in exercising. The project is based on the experience with the Pilates method, its positive influence on the core muscle strengthening and stretching, on the posture and the muscle dysbalance removal. It also reacts to the interest of university students in Body and Mind exercise forms. The newly established course will be integrated in the regular compulsory and optional semestral offer of the sports courses at the Sports University Centre in the spring term 2016. The course will be taught both in Czech and English language, and it will be offered to Czech students and foreign students coming to the university to study their studying programmes in English here. The ground of the course is the Pilates method, but it focuses on the exercise with rollers primarily. The exercise is enriched with the fascia-oriented training, which is a new kind of exercise based on the use of different stretching methods. The fascia-oriented exercise is gradually being introduced in various sports fields, mainly abroad so far. The opening of the new course was also initiated by the university students’ increasing concern in the modern and interactive conception of the sports education based on the remedial exercise. This is in accordance with the long-term goal of the university to support students’ active and healthy lifestyle, and to encourage university students for the body and health care, and the health prevention.
Rollpilates
The name Rollpilates consists of two words. The word roll means rolling, wheeling and Pilates is a widely spread and popular exercise method. Rollpilates is a system combining Pilates and the fascia-oriented training, whose ground is based on various types of stretching, and which incorporates rollers into the system.

Pilates
The basis of Rollpilates in the Pilates method. Its founder J.H.Pilates (1880-1967) was born in Germany and in 1926 left for New York where he opened his exercise studio with the support of his wife. Their first clients were dancers mainly, but sportspeople, actors, actresses and higher-class people started coming soon too.

The method became very popular because it is a complex exercise set suitable for everybody without any age, fitness or skill restrictions. The programme is suitable for beginners, pre-intermediate or advanced individuals. The emphasis is put on the correct posture, breathing and the core stabilization. The core muscle (powerhouse) initiation is the first step in Pilates. The method involves lateral breathing, which helps to activate the abdominal muscle during exercising. We should never hold the breath. We should inhale through the nose and exhale through the mouth, even when doing the most difficult exercise. The Pilates system helps to correct posture and muscle dysbalances, to create new and correct locomotory stereotypes without any muscle tension. It supports the fitness, and it shapes the body. Another goal is to balance both body and mind.

Pilates is used for some treatments in rehabilitation, by sportspeople in their training and it is popular in the public. In its basic form it is a kind of exercise on mats. To improve the quality and increase the efficiency, different types of equipment and sports aids are used. Various balance aids are popular these days to increase the instability. They support better the involvement of the core muscle system and increase the level of the difficulty of exercise. People should master the basic versions of the exercise correctly first, because incorrect exercising might cause wrong breathing, dysbalances and other health problems. The system was really well-developed by Joseph Pilates, but it is constantly enriched with a new scientific knowledge. The Pilates lectures have opened the system to modern inputs and they are incorporating the knowledge of the fascia-oriented training in it nowadays too.
The influence of the Integrated Systems Model (ISM) by Diane Lee, the Canadian therapist, who introduced new information about the core stabilization, the connective tissue and the fascial network, brought new trends into Pilates. The Fascial-Oriented Pilates Training started in 2001 and the system is enriched by the training of the neuromyofascial net. In accordance with the Pilates and Fascia-Oriented Training principles new movement sequences are formed and long myofascial chains are involved in the exercise process. The movements are multi-directional and their rhythm, frequency and pace change. It is a young system, which is still in progress and it aims to establish a comprehensive programme working with complex neuromyofascial meridians.

Stretching

Stretching is the basics of the fascial fitness, so we would like to introduce it a bit deeper. Originally, stretching is an English word meaning “protraction, expansion, elongation, stretch”. It is a special kind of exercise which extends flexibility and mobility, helps to prepare the body for motion load and strain, but it also prevents against injuries.

According to Buzková (2006) the main goal of stretching is “to stretch muscles optimally and to develop the range of motion without any negative effects, to decrease muscular tension after motion activities and to maintain muscles flexibility.” It optimises the shape of the neuro-muscular system before sports performances, prevents muscles from their possible injuries and some muscular diseases. It also supports the prevention of joints. Stretching prepares the body for the strain and locomotion and sports performance.

Stretching Types

According to Nelson & Kokkonen (2007), stretching may be divided into four basic kinds:

- Static stretching
- Dynamic stretching
- PNF stretching (proprioceptive neuromuscular facilitation)
- Ballistic stretching

Besides the above mentioned types, Buzková (2006) defines some other stretching types:
- Active stretching
- Passive stretching
- PIR method (post-isometric relaxation)
- Rhythmic stretching
- Repetitive stretching
- Power stretch
- Balance stretch

Nelsona & Kokkonen (2007) Stretching methods

Static stretching
It is a stretching method which does not require much energy expenditure and gives enough time to “shift” the possibilities of the stretch reflex. The method uses dwells and has two parts. First, the muscular tension is released and consequently the flexibility is increased. The danger of injury is very low during the static stretching. The muscle is stretched ultimately and then, the dwell for 20 seconds – 2 minutes is recommended according to some reference sources. In the static stretching to hold the breath is not advisable. The range of motion is extended when you breathe out. The static stretching can be used for the improvement of flexibility (Alter, 1994, Buzková, 2006).

Dynamic stretching
Dynamic stretching is a pointed kind of stretching, which uses the kinetic energy, and where we fluently move from one pose to another. The controlled moves of the given range and speed predominate. Dynamic stretching is preferred more and more for warm-ups, because it is suitable for their specific requirements. In this kind of stretching we gradually increase the speed of movement or the range of motion, or both these aspects simultaneously. This is a relatively new stretching method which is used for the improvement of the joint mobility and it can also be used for the lengthening of warmed-up muscles, if it is necessary to maintain the increased pulse rate. It requires more repetitions. The advantages of dynamic stretching are the possibilities to transfer movement patterns and the range of motion to given sports activities and to improve dynamic flexibility (Buzková, 2006, Cacek & Bubníková, 2009).

PNF Stretching (Proprioceptive Neuromuscular Facilitation)
It is an active stretching method connected with the method PIR. After the muscle contraction, the phase of release follows with the subsequent muscle lengthening. The strain loads the muscle in a static way first for 5-10 seconds, and then it relaxes for 3-5 seconds. Subsequently the muscle is lengthened in a static way again for 10-15 seconds. When dwelling in the pose it is essential to breathe in. When releasing or moving for another pose it is essential to breathe out. This is probably the most effective stretching method, which is not used enough and which deserves more attention and a wide use (Buzková 2006, Cacek, Grasgruber, Bubníková & Strachová, 2008). A certain disadvantage of the method is that it is time-consuming and to perform the method correctly, a high level of proprioception is vital (Slomka & Regelin, 2008).
Ballistic stretching

It is a swinging and springing kind of stretching, where the impulse is applied at the beginning of movement and then it is performed in an inertial way. One of the disadvantages of this method is a short period of dwelling in the ultimate pose. Another substantial disadvantage is the high probability of possible injuries. It is vital to perform this method very carefully. Primarily the method is used by professional athletes. It perfectly prepares warmed-up muscles for the load, but it does not extend the range of motion and flexibility (Buzková, 2006).

Other stretching methods and their characteristics according to Buzková (2006)

Active Stretching

Stretching is performed without any extrinsic power influence. It is a method where dwelling in the ultimate pose is performed intentionally. The period of 30-60-second dwelling in the ultimate pose is advised.

Passive Stretching

The method is used in rehabilitation and it is performed with the use of the extrinsic power influence (the body weight plus the other person). When the method is applied, consideration and communication between the involved people is absolutely essential, because it prevents possible muscle damage.

PIR Method

The post isometric contraction is performed first, with no changes in the muscle fibre length during the muscle activation. This phase lasts about 8 seconds with the subsequent release for about 3 seconds. Then the muscle lengthening for 20-30 seconds is employed.

Rhythmic Stretching

It is a combination of the static and dynamic stretching. There are several ways of its performance. Most frequently the first phase involves dynamic stretching followed with the static one. After several repetitions, the movements stop, and the person stays in the static pose.

Repetitive Stretching

Mini-bounces are employed in the ultimate position, which means that muscles are elongated when they are active.

Power stretch

The core muscle activation and stabilization is stressed during exercising. The muscles in the lumbar area are activated, and the spine is elongated when inhaling. Power stretch involves dynamic and passive stretching, the power of antagonists is involved as well as the changes of the close and open positioning of pelvis. Besides flexibility, the method develops the power and balance, improves muscle dysbalances and supports the posture.

Balance stretch

To increase demands and to stimulate deep core muscles, the method uses balance poses. If we want to increase the demands more, it is possible to extend the range of motion, to close the eyes, or to involve the arms.

Static vs. Dynamic Stretching

Polemics about the suitability and appropriateness of stretching before sports performances are quite frequent these days. Generally, the use of the static stretching before the sports performance, the development of flexibility with the use of static stretching after the sports performance and the
positive influence of dynamic stretching focused on the dynamic power before the sports performance are accepted (Cacek & Bubníková, 2009).

Static stretching applied after the sports performance has a positive impact on the improvement of flexibility in the long-term context. Because stretching is employed after the performance, it does not have any negative impacts on it. The optimally developed flexibility enables to perform the intended movement at the full range. This kind of stretching should be involved in the training process regularly. Nevertheless it should not be a part of warm-up, but it should be employed after the sports performance (Cacek & Bubníková, 2009, Foretník 2010).

Fascialfit – Fascia-oriented training
Connective tissue works in the human body as one interconnected whole, it is omnipresent and goes deeply from the surface into the core, where it wraps all body structures and organs. It is spread from top of our head to the tips of the toes. Its cells vary in the shape and function, but they support our anatomical integrity. The fascial network plays an inevitable role in every human body. It interconnects its structures and organs and enables them to glide smoothly against each other thanks to its elasticity, plasticity and flexibility. It has many other functions in the body, such as supporting or mechanical one. It supports the intake of nutrients and the waste substance flow, the water circulation. It protects the body against the outer unwelcome impacts. In the course of life the tissue undergoes histological, morphological and other changes. Negative impacts, diseases, injuries, stress, painful and inflammatory processes influence its condition. They reduce its elasticity and some types of the connective tissue even become matted. Research findings show that a healthy fascial network is highly elastic and if the elasticity decreases it is possible to train it with the use of the correctly selected exercise. It remolds its architecture, rehydrates the tissue and restores the elasticity. The exercise also supports the involvement of the fascial kinetic energy in locomotion, which improves the locomotive performance and capacity.

How exactly can we train the fascial network? The problem is still under wide research, both in the lab and gym. But we know that we can train this net. This training does not bring any new type of exercise, we use what we know, and we only adopt these well known kinds of exercise slightly. The training has its basic principles formed in accordance with the research findings done in the field of the connective tissue.

It is sufficient to train for 15-20 minutes twice or three times a week only. The fascial net reacts more slowly, the first changes come after three months and the whole process can take up to two years. The induced changes are more durable than in the muscular tissue, though.

The fascia-oriented training can have different goals and these tasks influence the training structure. We use and change different forms of stretching to improve the elasticity, remodel the tissue architecture, or to learn how to use the fascial kinetic energy more efficiently. Long-lasting utilization of one stretching form and endless repetitions of the same exercise is not suitable. We use slow and fast dynamic stretching, the active and passive, bouncing, rhythmical and repetitive forms of stretching. It is vital to engage the balance exercise to increase a level of the difficulty, to offer more variety and diversity and to stimulate proprioception. The creativity and experience of lecturers is desirable, because slight modifications are effective. The longest possible myofascial chains should be involved and stretched, multi-directional motions and rotations and twists applied. One exercise battery without any modifications does not work in the fascia-oriented training. Rollers and other balance aids ought to be integrated into the stretching sequences. The utilization of a specific self-massage is included if the fascial rehydration and release are focused on. It is a slow massage in which an individual positions themselves on top of a roller and rolls over it. The slow, fluent and multi-
directional accomplishment as well as the appropriate loading is very important and absolutely essential. The loading can be regulated by different positioning of various body areas on a roller. The massage might seem a bit painful first, but shortly the first discomfort disappears, and the conditions of the fascial network improve, soreness retreats. The fascial release can be also performed without the roller. The slow, pleasant, smooth, relaxed and nonviolent stretching in lying, sitting or standing poses with multi-directional motions and rotations fulfils this function too. The concentration on the deep breathing and the feel of a mat, chair or ground should be involved, yawning is advisable. This stretching is similar to the stretching activity we naturally do in bed in the morning after waking up.

Main principles
Gracefulness
Motions should be utilized in a relaxed, fluent, soft and quiet way with minimum force. Jerky movements, violent and rash changes or excessive loading does not support the process of the fascial network remodelling.

Variability
The fascia-oriented training means using as much variability when exercising as possible, which means modifications, changes in rhythm, pace and positioning. Repetitive, recurring and cyclical programmes are not appropriate.

Comprehensiveness
Complex movements are significant. We should not train isolated muscles or muscle groups, but the longest possible myofascial chains.

Consciousness
Movements are performed consciously. We should fully concentrate on the performance. There are many proprioceptors in the fascial network and their activation influences the restoration of the net.

Preparatory countermovement
If we want to consume the kinetic energy of the fascia, it is advisable to start movements with the preparatory countermovement. We start it with slight pretensioning it the opposite direction. The fascia becomes actively pretensioned and its dynamic recoil action supports the muscle work and enhances the performed movement.

Fascial Rebound and Fascial Stretch
These principles include stretching. Slow dynamic stretching is used to stretch the tissue and fast dynamic stretching is used to involve the kinetic energy of the fascia in the process of locomotion, exercise or the sports performance.

Foam rollers
The first person who used rollers in physiotherapy was Mr. Feldenkreis, his first rollers were wooden. In the 1970’s he met foam rollers and started to use them. Another promoter was a physiotherapist Mike Clark, who worked with professional athletes. He used rollers for acupressure, and later recommended them to athletes to release the muscular stiffness and tension and promoted them as a reasonably cheap alternative to self-treatment and soft tissue therapies. He also used rollers to work with trigger points, small tight areas within the muscle tissue, painful in palpation. Today foam rollers are used in various types of exercise for self-myofascial massage or as sports balance aids. They enable more effective core muscle work, promote the blood circulation, and thus improve the intake of nutrients and take waste substances away in cells more efficiently. They support stretching and body shaping, help to unblock problems in the neck spine area. The massage with rollers releases muscles and fascia, and restores balance in the whole locomotive system.
Methodology of Rollpilates Exercise – how to practise

The objective of the material is not to provide concrete sets of exercise or lesson programmes; it aims to offer a collection of Pilates and fascia-oriented exercises enhanced with a possible foam roller application. Everyone can choose different exercises and design their own lesson of Pilates supplemented with fascia-oriented exercise parts.

The methodology of Rollpilates is based on the original Pilates system. Both Pilates exercise on mats and on rollers can only be effective, if the basic principles are constantly followed.

All movements in Pilates start in the core, which is also called Powerhouse or the power centre, and then gradually spread to peripheral parts of body. Each exercise starts with the activation of the core area and all following movements begin from this stabilized centre. The centre involves the abdominal muscles, the muscles in the low back and pelvis. The involvement of the muscle core in cooperation with the correct lateral breathing is the basic principle of the exercise. Pilates uses lateral breathing when you breathe into the low and back areas of the rib cage and so the abdomen is activated. The principles of accuracy and control are of high prominence, because the whole performance of each exercise is very important. The quality is preferred to quantity and so it is sufficient to repeat each exercise 5-10x. The improvement of fluency and accuracy rather than the increase in exercise repetition should be focused on. It is vital to follow the principle of concentration so that the training can be effective. Exercise visualization also helps to involve all required muscles in the performance.

New or advanced exercises should only gradually be included in the programme; the fulfilment of all principles is principal. The advance performance of exercises is advisable to involve after their basic variations are mastered. The use of foam rollers increases instability and exercises become more effective, but also more difficult. That is why the performance of the basic exercise variations should be mastered before using balancing tools to avoid any incorrect exercise performance and wrong breathing. On the contrary, in many exercises the use of a foam roller can help to understand and perform the exercise better. For example, foam rollers can help to give a feedback about the spine and pelvis placement, to feel the spine elongation and to breathe correctly in lying position.

The exercise battery is designed in accordance with the original Pilates system. It involves exercises for beginners as well as for intermediate gymnasts. Preparatory exercises and advanced variations are
included and so the battery can be used by different efficiency groups. It is suitable for both any sports training and everyday exercising.

Fascia-oriented exercise is designed as a separate chapter. This battery includes four video samples. The choreographies are inspirations of how to perform this exercise. The basics of it are different stretching types. The exercise influences the elasticity, architecture, hydration, proprioception of connective tissues and the production of their basic cells, fibroblasts. It also improves the use of fascial kinetic energy in locomotion and makes it more effective. It has an impact on the whole fascial network and its quality. The system has no given choreographies; it is based on the formation and use of different stretching sequences. It depends on the teachers or lecturers’ experience and knowledge. Slow, actively loaded dynamic stretching with rotation movements and undulations, bouncing and static or melting stretch should be involved to improve the tissue elasticity, to remodel its architecture, to enhance the fibroblast production. These stretching types can be performed separately and they can be combined, e.g. the legs perform a static stretch variation, the arms and torso stretch in a dynamic way employing rhythmical mini-bouncing, several repetitions of ballistic stretching are also advisable to include. To learn to involve the fascia kinetic energy in motion, smooth mini-bounces against a wall, chair or floor and a few swift, but smooth repetitions of ballistic stretching are also suitable to include. If performed vice versa, the torso and arms stretch in a static way and the legs perform the slow, dynamic, actively loaded stretch with rhythmical mini-bouncing, rotations, undulations and several repetitions of ballistic stretching. Mini-bouncing or ballistic stretching performed in ultimately stretched positions help to learn to involve and use the fascial kinetic energy in exercise and subsequently in locomotion. To perform the exercise correctly, it is important to know, understand and follow the fascia-oriented exercise principles, which are described in the theoretical part of the material. Fascial self-massage whose main goal is to rehydrate and release the tissue is also introduced in the exercise battery.

Fascia-oriented exercise can be included both at the beginning and at the end of Rollpilates lesson as a separate whole. However, its short sequences can be practised in all positions and you can fluently change from Pilates to fascia-oriented exercise any time during the whole lesson. The sequences do not need to take long, their duration from 10-15sec to 2 min is sufficient. The slow fascial self-massage should always be performed at the end of lesson.
Fascia-oriented exercise is quite nouveau in the world of sports and PE and is still developing. However, research and scientific findings show that the fascial network can be trained and fascia-oriented exercise has positive effects on the tissue. It can enhance any sport or exercise and thanks to it the locomotion becomes more accurate and healthier.

</tr>
<tr>
<td>Precision Points</td>
<td>do NOT move your lower back, keep a perfectly still torso and the pelvis motionless, do NOT tilt the head back. If you cannot keep the position, reduce the range of motion</td>
</tr>
<tr>
<td>Purposes</td>
<td>stabilization and strengthening of the core muscles, strengthening and stretching of the leg muscles</td>
</tr>
</tbody>
</table>
Photo 1 lie with the sacrum on the roller, lengthen both legs long to the ceiling, the feet pointed, the arms long to the sides with the palms holding the roller.

Photo 2 breathe in and lower long legs a little, breathe out and move the legs back.
Photo 3 with the feet flexed

Photo 4 breath in and lower long legs a little, breath out and move the legs back
Photo 5 VP lie with the back on the roller, lengthen both legs long to the ceiling, the feet flexed, the arms long to the sides.

Photo 6 breathe in and lower long legs a little, breathe out and move the legs back.
### Scissors

| **Setup** | lie with the sacrum on the roller, lengthen both legs long to the ceiling, the feet pointed, the arms long to the sides, the palms holding the roller (photo 1) |
| **Action** | move one leg toward your shoulders, while letting the other one lower half way to the floor, the feet pointed (photo 2) or flexed (photo 3) |
| **Modification 1** | lie with the back on the roller, lengthen both legs long to the ceiling, the feet pointed, the arms long to the sides on the ground (photo 4); move one leg toward your shoulders, while letting the other one lower half way to the floor, the feet pointed (photo 5-6) or flexed |
| **Modification 2** | lie with the back on the roller, lengthen both legs long to the ceiling, the arms long to the sides on the ground, switch moving the legs to the sides, the feet pointed (photo 7) or flexed (photo 8) |
| **Precision Points** | breathe regularly, do NOT hold the breath. If you move the legs too much, you cannot keep the powerhouse; do NOT move your lower back, keep a perfectly still torso and the pelvis motionless, do NOT tilt the head back |
**Purposes**

stabilization and strengthening of the core muscles, strengthening and stretching of the leg muscles, the improvement of coordination

*Photo 1* lie with the sacrum on the roller, lengthen both legs long to the ceiling, the feet pointed, the arms long to the sides, the palms holding the roller

Photo 9 you can do this exercise with the shins on the roller
Fascial Massage

Rolling with foam rollers is a kind of massage, when you roll over various areas of your body using our bodyweight, which brings the connective tissue and muscular release (self-myofascial release). Rolling means slow and fluent multi-directional motions. You should stay for 20-30 seconds in tight or painful areas, letting your bodyweight work, or change the position to increase the press slightly and should rotate a bit in a sore area. In the beginning you can feel the massage in some areas a bit painful. You should learn to listen to your body to distinguish if the pain is sharp and dart. This kind of pain needs medical treatment. The massage helps if the pain signalizes tissue stiffness. This kind of pain finally disappears if you perform massage in the long term. The massage of the whole body is time consuming, but you can focus on one or two smaller areas of the body, which are stiffed more, after each workout. Remember to breathe regularly as performing the massage, do NOT hold breath. You can use any roller, they differ in their length and firmness. If possible, choose a less firm roller first and gradually adapt for firmer ones and the ones with a coarsen surface.

| Precision Points | Do NOT use the self-myofascial massage every day, 2-3 times a week is appropriate. The changes in the tissues are based on the production of collagen, which is subordinate to biochemical principles. One of them is a 1-2 day rest phase after massage. If you roll every day, the tissue is not given a sufficient time and chance to release, rehydrate and remodel. Be persistent instead, the changes come after six months – two years of a regular and constant exertion. |
| Purpose | relaxed, hydrated and correctly modelled soft tissue enables smooth glides of all body organs and structures. Rolling is one of the methods, which can help as a prevention of injuries in the locomotory system. It also accelerates the healing process after injury and return to a healthy and fully functional organism. |

Foot massage

| Action | Place one foot on the roller (photo 1) and roll over the foot. Because of the size, the foot massage is better to perform with a small ball. Start pushing the heel into the ball (photo 2) and then roll forward toward particular toes separately (photo 3-4) and back. As rolling, you can stop in a tender place, letting your bodyweight work, or move the foot over the roller to the sides with the heel on the ground (photo 5) or slightly off. |
Photo 1 place one foot on the roller

Photo 2 start pushing the heel into the ball
Photo 3 roll forward toward particular toes separately and back

Photo 4 roll forward toward particular toes separately and back
**Photo 5** as rolling, you can stop in a tender place, letting your bodyweight work, or move the foot over the roller to the sides with the heel on the ground or slightly off

### Calf massage

<table>
<thead>
<tr>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sit with the legs positioned on top of the roller parallel or crossed (photo 6) and roll slowly. You can increase the press, if sitting off the ground, the legs parallel (photo 7) or crossed (photo 8). The easier position is to sit with one leg other roller and the other bent with the foot on the ground. Stay in areas of tightness and rotate at ankle (photo 9) or move the calf over the roller to the sides and multi-directionally (photo 10-12).</td>
</tr>
</tbody>
</table>

Photo 8 you can increase the press, if sitting off the ground, the legs crossed.

Photo 9 stay in areas of tightness and rotate at ankle.
Photo 10 move the calf over the roller to the sides and multi-directionally

Obr 11 move the calf over the roller to the sides and multi-directionally
Shin and peroneal massage

<table>
<thead>
<tr>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Position your shins on top of the roller (photo 13) and use the weight of your body to slowly roll back and forth over it. The easier position is to kneel down, one shin on the roller (photo 14). Then sit and place the peroneal area on the roller, roll the peroneal area over the roller multi-directionally (photo 15).</td>
</tr>
</tbody>
</table>
Photo 13 position your shins on top of the roller

Photo 14 the easier position is to kneel down, one shin on the roller
**Photo 15 sit and place the peroneal area on the roller, roll the peroneal area over the roller multi-directionally**

**Masáž zadní a vnější části DK (zadní a vnější část stehna)**

<table>
<thead>
<tr>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sit with the thighs on the roller (photo 16) and slowly roll back and forth over it. The back thigh is a big area, so divide it into two halves and roll the area near the knee joint first and then roll the upper area. The outer thigh is a problematic and highly stiff, painful area in most people. Divide this area into two parts too and focus on the lower (more painful) area first, then continue rolling the upper area (photo 17). Roll really slowly, stay longer and use multi-directional motions.</td>
</tr>
</tbody>
</table>
Photo 16 sit with the thighs on the roller and slowly roll back and forth over it

Photo 17 divide this area into two parts too and focus on the lower (more painful) area first, then continue rolling the upper area
Front and inner thigh massage

Position yourself on top of the roller with the quadriceps on it (photo 18) and slowly roll back and forth over it. The area is big, so divide it into two parts and roll over the lower area, then the upper one. The easier position is with one leg bent and positioned on the ground (photo 19). Next place the roller under the inner area of the thigh (photo 20) and roll near the knee first and closer to the hip later.

<tbody>
<tr>
<td>Sit on top of the roller (photo 21). You can cross your legs to increase the press, if necessary (photo 22). Here you can find another problematic zone – the deep rotators of the hip joints placed in the pelvic floor – it is more effective to massage it with a small ball (photo 23). The motions should be tiny. The firmer the ball is, the deeper it works.</td>

Back massage

**Action**

Sit with the roller positioned just above the low back (photo 24), roll the low area of the back forth and back over it, and to the sides (photo 25-26). Next roll the upper area of the back (photo 27). The easier position is with the arms folded over your chest (photo 28).

Photo 27 roll the upper area of the back

Photo 28 the easier position is with the arms folded over your chest
Torso, arm and neck massage

**Action**

Lie on the side on the roller and roll the side of your torso as far as the armpits (photo 29). Place the roller under the arm and its back area (photo 30). Lie on the stomach with the roller under the arm and roll the front area of the arm (photo 31). Lie on your back, the roller under the neck (photo 32) and slowly turn your head to the sides (photo 33-34), and use small multi-directional motions. The area of the shoulder can be massaged with a small ball (photo 35-36).

### Fascial Stretch

#### Setup

- sit with the legs crossed

#### Action

- sit with the legs crossed and perform slow and fluent dynamic multi-directional stretching of the torso and arms, and rotations in the wrists and finger joints. Sit with the legs extended and continue stretching the torso, arms and legs in a slow, fluent dynamic multi-directional way. Sit with the legs extended and apart, stretch the torso, arms and legs multi-directionally, dynamically and fluently. Roll like a ball from the sitting position dynamically, smoothly and fluently several times. When moving back to seat, change the positioning of the legs. Swing to squat several times and finally swing to standing position.

#### Precision Points

The choreography is a sample of fascia-oriented exercise focusing on the improvement of fascial network elasticity. It includes a dynamic, actively loaded stretching sequence. Trunk-bending sideways, forward bends and rotations do not have to be performed exactly according to this video. The choreography is only an inspirational example. If the exercise focuses on the improvement of fascial network elasticity, the principle of slow, smooth, elegant and fluent, actively loaded dynamic stretching must be followed. The longest possible myofascial meridians, rotations in the spine, big and small joints employed in the movement should be performed and practised.

#### Purposes

- improvement of fascial network elasticity

---

### Fascial Stretch and Elasticity

#### Setup

- stand up

#### Action

- In standing position stretch of the torso and arms multi-directionally, involve side-bends, forward and backward bends, rotations in the spine, wrists and finger joints. Slowly roll forward and bend the knees a bit. Undulate in the torso and simultaneously stretch the arms. Bend the knees more and continue stretching the arms. Move to standing position with the legs apart. Transfer weight to the right and left alternately and stretch the arms dynamically, fluently and multi-directionally at the same time. Finally roll up to standing position.

---

**Video:**

**Precision Points**

The choreography is a sample of fascia-oriented exercise focusing on the improvement of fascial network elasticity. It includes a dynamic, actively loaded stretching sequence. Trunk-bending sideways, forward bends and rotations do not have to be performed exactly according to this video. The choreography is only an inspirational example. If the exercise focuses on the improvement of fascial network elasticity, the principle of slow, smooth, elegant and fluent, actively loaded dynamic stretching must be followed. The longest possible myofascial meridians, rotations in the spine, big and small joints employed in the movement should be performed and practised.

**Purposes**

Improvement of fascial network elasticity.

**Fascial Stretch and Rebound 1**

<table>
<thead>
<tr>
<th><strong>Setup</strong></th>
<th>Stand up</th>
</tr>
</thead>
</table>

| **Action** | Move the right/left foot over the massage ball and press the ball with the foot in standing position. Bend the knees slightly, transfer weight to the sides, forward and backward alternately and roll the feet smoothly. Move from knee banding to the position of standing tiptoe several times. Stay with the knees bent and swing several times. Turn to the left gradually while taking forward and backward steps in the right leg. Stretch the arms upward and roll the foot on the mat smoothly and multi-directionally. Keep the foot on the mat (the leg is stretched in a static way) and stretch the right/left arm dynamically. Move back to the central position and switch to the other leg. Stay in the central position with the knees bent and swing several times. Turn left, roll and bounce the right foot, change the positioning of the foot and the rhythm, involve the work of the arms. Next include dynamic ballistic stretching: kick and bend the right leg with simultaneous fast, actively loaded flexion of the torso when the muscles in the low back are pre-tensioned. Then switch to the other leg. |

| **Precision Points** | The choreography is a sample of fascia-oriented exercise focusing on the improvement of fascial network elasticity. It includes actively loaded dynamic stretching. The exercise employs foot-massage balls, which activate the whole locomotory system and different receptors present in the muscular and connective tissue of the feet. Mini-bounces activate the employment of fasciae in dynamic motion and teach how to involve their kinetic energy. The mini-bounces should be performed smoothly, |
rhythmically and dynamically. The longest possible myofascial meridians should be employed.

**Purposes**

improvement of fascial network proprioception and elasticity, enhancement of the use of fascial kinetic energy in dynamic movement.

---

**Fascial Stretch and Rebound 2**

<table>
<thead>
<tr>
<th><strong>Setup</strong></th>
<th>moderate knee band</th>
</tr>
</thead>
</table>

**Action**

swing several times when standing with the knees slightly bent. Roll the feet smoothly and change their positioning. When standing with the knees slightly bent (the calves are stretched in a static way), stretch the arms and torso dynamically. Move to the position of pyramid and roll the feet smoothly. Move the right/left leg slightly backward alternately, involve mini-bouncing of the right/left foot. Perform the undulation and rotation of the torso and smooth multi-directional mini-bouncing in the feet. Involve various steps and jumps, draw inspiration from the animal realm (imitate crabs, cats, spiders etc.). Move the legs towards the arms finally and roll up. Stretch the arms and torso slowly and smoothly.

**Precision Points**

the choreography is a sample of fascia-oriented exercise focusing on the employment of fasciae in dynamic motion and the improvement of their kinetic energy utilization in bouncing and jumping. It includes actively loaded dynamic stretching. Mini-bounces activate the employment of fasciae in dynamic motion and teach how to involve their kinetic energy. The mini-bounces should be performed smoothly, rhythmically and dynamically. The longest possible myofascial meridians should be employed.

**Purposes**

enhancement of the use of fascial kinetic energy in dynamic movement, improvement of fascial network elasticity
