## CHAPTER 17

## Investment

## MACROECONOMICS N. GREGORY MANKIW

PowerPoint ${ }^{\circledR}$ Slides by Ron Cronovich

## In this chapter, you will learn...

- leading theories to explain each type of investment
- why investment is negatively related to the interest rate
- things that shift the investment function
- why investment rises during booms and falls during recessions

## Three types of investment

- Business fixed investment: businesses' spending on equipment and structures for use in production.
- Residential investment: purchases of new housing units (either by occupants or landlords).
- Inventory investment: the value of the change in inventories of finished goods, materials and supplies, and work in progress.
CHAPTER 17 Investment

## Understanding business fixed investment

- The standard model of business fixed investment:
the neoclassical model of investment
- Shows how investment depends on
- MPK
- interest rate
- tax rules affecting firms

## Two types of firms

- For simplicity, assume two types of firms:

1. Production firms rent the capital they use to produce goods and services.
2. Rental firms own capital, rent it to production firms.

## In this context, <br> "investment" is the rental firms' spending on new capital goods.

## The capital rental market

Production firms must decide how much capital to rent.

Recall from Chap. 3: Competitive firms rent capital to the point where $M P K=R / P$.
real rental price, $\boldsymbol{R} / \boldsymbol{P}$
capital supply
capital demand (MPK)

$$
\begin{aligned}
& \text { equilibrium } \\
& \text { rental rate }
\end{aligned}
$$

## Factors that affect the rental price

For the Cobb-Douglas production function,

$$
\boldsymbol{Y}=\boldsymbol{A} \boldsymbol{K}^{\alpha} \boldsymbol{L}^{1-\alpha}
$$

the MPK (and hence equilibrium $R / P$ ) is

$$
\frac{\boldsymbol{R}}{\boldsymbol{P}}=\boldsymbol{M P K}=\alpha \boldsymbol{A}(\boldsymbol{L} / \boldsymbol{K})^{1-\alpha}
$$

The equilibrium $R / P$ would increase if:

- $\downarrow \boldsymbol{K}$ (e.g., earthquake or war)
- $\uparrow L$ (e.g., pop. growth or immigration)
- $\uparrow \boldsymbol{A}$ (technological improvement, or deregulation)

## Rental firms' investment decisions

- Rental firms invest in new capital when the benefit of doing so exceeds the cost.
- The benefit (per unit capital):
$R / P$, the income that rental firms earn from renting the unit of capital to production firms.

## The cost of capital

Components of the cost of capital: interest cost: $\mathbf{i} \times \boldsymbol{P}_{\mathbf{K}}$, where $\boldsymbol{P}_{\mathbf{K}}=$ nominal price of capital depreciation cost: $\boldsymbol{\delta} \times \boldsymbol{P}_{\mathbf{K}}$, where $\delta=$ rate of depreciation capital loss: $-\Delta \boldsymbol{P}_{\mathbf{K}}$
(a capital gain, $\Delta \boldsymbol{P}_{\boldsymbol{K}}>0$, reduces cost of $\boldsymbol{K}$ )
The total cost of capital is the sum of these three parts:

## The cost of capital

Nominal cost of capital

$$
=\boldsymbol{i} \boldsymbol{P}_{\boldsymbol{K}}+\delta \boldsymbol{P}_{\boldsymbol{K}}-\Delta \boldsymbol{P}_{\boldsymbol{K}}=\boldsymbol{P}_{\boldsymbol{K}}\left(\boldsymbol{i}+\delta-\frac{\Delta \boldsymbol{P}_{\boldsymbol{K}}}{\boldsymbol{P}_{\boldsymbol{K}}}\right)
$$

Example: car rental company (capital: cars) Suppose $P_{\mathrm{K}}=\$ 10,000, i=0.10, \delta=0.20$, and $\Delta \boldsymbol{P}_{\mathrm{K}} / \boldsymbol{P}_{\mathrm{K}}=0.06$

Then, interest cost $=\$ 1000$

$$
\text { depreciation cost }=\$ 2000
$$

capital loss = - \$600 total cost $=\$ 2400$

## The cost of capital

For simplicity, assume $\Delta \boldsymbol{P}_{\mathbf{K}} / \boldsymbol{P}_{\mathbf{K}}=\pi$.
Then, the nominal cost of capital equals

$$
P_{\mathrm{K}}(\mathrm{i}+\delta-\pi)=P_{\mathrm{K}}(r+\delta)
$$

and the real cost of capital equals $\frac{\boldsymbol{P}_{\boldsymbol{K}}}{\boldsymbol{P}}(\boldsymbol{r}+\delta)$
The real cost of capital depends positively on:

- the relative price of capital
- the real interest rate
- the depreciation rate

CHAPTER 17 Investment

## The rental firm's profit rate

A firm's net investment depends on its profit rate:

$$
\text { Profit rate }=\frac{\boldsymbol{R}}{\boldsymbol{P}}-\frac{\boldsymbol{P}_{\boldsymbol{K}}}{\boldsymbol{P}}(\boldsymbol{r}+\delta)=\boldsymbol{M} \boldsymbol{P} \boldsymbol{K}-\frac{\boldsymbol{P}_{\boldsymbol{K}}}{\boldsymbol{P}}(\boldsymbol{r}+\delta)
$$

- If profit rate >0, then increasing $K$ is profitable
- If profit rate $<0$, then the firm increases profits by reducing its capital stock
(i.e., not replacing capital as it depreciates.)

## Net investment \& gross investment

## Hence,

$$
\text { net investment }=\Delta \boldsymbol{K}=\boldsymbol{I}_{\boldsymbol{n}}\left[\boldsymbol{M} \boldsymbol{P K}-\left(\boldsymbol{P}_{\boldsymbol{K}} / \boldsymbol{P}\right)(\boldsymbol{r}+\boldsymbol{\delta})\right]
$$

where $\boldsymbol{I}_{n}[$ ] is a function that shows how net investment responds to the incentive to invest.

Total spending on business fixed investment equals net investment plus replacement of depreciated $\boldsymbol{K}$ :

$$
\begin{aligned}
\text { gross investment } & =\Delta \boldsymbol{K}+\delta \boldsymbol{K} \\
& =\boldsymbol{I}_{n}\left[\boldsymbol{M P K}-\left(\boldsymbol{P}_{\boldsymbol{K}} / \boldsymbol{P}\right)(\boldsymbol{r}+\delta)\right]+\delta \boldsymbol{K}
\end{aligned}
$$

## The investment function

$$
\boldsymbol{I}=\boldsymbol{I}_{n}\left[\boldsymbol{M P K}-\left(\boldsymbol{P}_{\boldsymbol{K}} / \boldsymbol{P}\right)(\boldsymbol{r}+\boldsymbol{\delta})\right]+\boldsymbol{\delta} \boldsymbol{K}
$$

An increase in $r$

- raises the cost of capital
- reduces the profit rate
- and reduces investment:

## The investment function

$$
\boldsymbol{I}=\boldsymbol{I}_{n}\left[\boldsymbol{M P K}-\left(\boldsymbol{P}_{\boldsymbol{K}} / \boldsymbol{P}\right)(\boldsymbol{r}+\delta)\right]+\delta \boldsymbol{K}
$$

An increase in MPK or decrease in $\boldsymbol{P}_{\mathbf{K}} / \boldsymbol{P}$

- increases the profit rate
- increases
investment at any given interest rate
- shifts $\boldsymbol{I}$ curve to the right.

## Taxes and investment

## Two of the most important taxes affecting investment:

1. Corporate income tax
2. Investment tax credit

## Corporate Income Tax: A tax on profits

Impact on investment depends on definition of "profit"

- In our definition (rental price minus cost of capital), depreciation cost is measured using current price of capital, and the CIT would not affect investment
- But, the legal definition uses the historical price of capital.
- If $P_{\mathbf{K}}$ rises over time, then the legal definition understates the true cost and overstates profit, so firms could be taxed even if their true economic profit is zero.
Thus, corporate income tax discourages investment.
CHAPTER 17 Investment

## The Investment Tax Credit (ITC)

- The ITC reduces a firm's taxes by a certain amount for each dollar it spends on capital.
- Hence, the ITC effectively reduces $\boldsymbol{P}_{\mathbf{K}}$ which increases the profit rate and the incentive to invest.

## Tobin's $q$

## $\boldsymbol{q}=\frac{\text { Market value of installed capital }}{\text { Replacement cost of installed capital }}$

- numerator: the stock market value of the economy's capital stock.
- denominator: the actual cost to replace the capital goods that were purchased when the stock was issued.
- If $\boldsymbol{q}>1$, firms buy more capital to raise the market value of their firms.
- If $\boldsymbol{q}<1$, firms do not replace capital as it wears out.

## Relation between $\boldsymbol{q}$ theory and neoclassical theory described above

$$
\boldsymbol{q}=\frac{\text { Market value of installed capital }}{\text { Replacement cost of installed capital }}
$$

- The stock market value of capital depends on the current \& expected future profits of capital.
- If $M P K>$ cost of capital, then profit rate is high, which drives up the stock market value of the firms, which implies a high value of $\boldsymbol{q}$.
- If MPK < cost of capital, then firms are incurring losses, so their stock market values fall, so $\boldsymbol{q}$ is low.

## The stock market and GDP

Reasons for a relationship between the stock market and GDP:

1. A wave of pessimism about future profitability of capital would

- cause stock prices to fall
- cause Tobin's $\boldsymbol{q}$ to fall
- shift the investment function down
- cause a negative aggregate demand shock

## The stock market and GDP

Reasons for a relationship between the stock market and GDP:
2. A fall in stock prices would

- reduce household wealth
- shift the consumption function down
- cause a negative aggregate demand shock

## The stock market and GDP

Reasons for a relationship between the stock market and GDP:
3. A fall in stock prices might reflect bad news about technological progress and long-run economic growth.
This implies that aggregate supply and full-employment output will be expanding more slowly than people had expected.

## The stock market and GDP

## Alternative views of the stock market: The Efficient Markets Hypothesis

- Efficient Markets Hypothesis (EMH):

The market price of a company's stock is the fully rational valuation of the company, given current information about the company's business prospects.

- Stock market is informationally efficient: each stock price reflects all available information about the stock.
- Implies that stock prices should follow a random walk (be unpredictable), and should only change as new information arrives.
CHAPTER 17 Investment

## Alternative views of the stock market: Keynes's "beauty contest"

- Idea based on newspaper beauty contest in which a reader wins a prize if he/she picks the women most frequently selected by other readers as most beautiful.
- Keynes proposed that stock prices reflect people's views about what other people think will happen to stock prices; the best investors could outguess mass psychology.
- Keynes believed stock prices reflect irrational waves of pessimism/optimism ("animal spirits").

## Alternative views of the stock market: EMH vs. Keynes's beauty contest

Both views persist.

- There is evidence for the EMH and random-walk theory (see p.498).
- Yet, some stock market movements do not seem to rationally reflect new information.

## Financing constraints

- Neoclassical theory assumes firms can borrow to buy capital whenever doing so is profitable.
- But some firms face financing constraints: limits on the amounts they can borrow (or otherwise raise in financial markets).
- A recession reduces current profits. If future profits expected to be high, investment might be worthwhile. But if firm faces financing constraints and current profits are low, firm might be unable to obtain funds.

## Residential investment

- The flow of new residential investment, $\boldsymbol{I}_{\boldsymbol{H}}$, depends on the relative price of housing $\boldsymbol{P}_{\boldsymbol{H}} / \boldsymbol{P}$.
- $\boldsymbol{P}_{\boldsymbol{H}} / \boldsymbol{P}$ determined by supply and demand in the market for existing houses.

## How residential investment is determined

(a) The market for housing
$\frac{\boldsymbol{P}_{H}}{\boldsymbol{P}}$
Supply

$\boldsymbol{K}_{\boldsymbol{H}}$
Stock of
housing capital

The equilibrium price of houses then determines residential investment:

## How residential investment is determined

## (a) The market for housing <br> (b) The supply of new housing

Flow of residential investment

## How residential investment responds to a fall in interest rates

(a) The market for housing

housing capital
(b) The supply of new housing

Flow of residential investment

## The tax treatment of housing

- The tax code, in effect, subsidizes home ownership by allowing people to deduct mortgage interest.
- The deduction applies to the nominal mortgage rate, so this subsidy is higher when inflation and nominal mortgage rates are high than when they are low.
- Some economists think this subsidy causes over-investment in housing relative to other forms of capital.
- But eliminating the mortgage interest deduction would be politically difficult.

## Inventory investment

## Inventory investment is only about

 $1 \%$ of GDP.Yet, in the typical recession, more than half of the fall in spending is due to a fall in inventory investment.

## Motives for holding inventories

1. production smoothing

Sales fluctuate, but many firms find it cheaper to produce at a steady rate.

- When sales < production, inventories rise.
- When sales > production, inventories fall.

## Motives for holding inventories

## 1. production smoothing

2. inventories as a factor of production

Inventories allow some firms to operate more efficiently.

- samples for retail sales purposes
- spare parts for when machines break down

## Motives for holding inventories

1. production smoothing
2. inventories as a factor of production
3. stock-out avoidance

To prevent lost sales when demand is higher than expected.

## Motives for holding inventories

1. production smoothing
2. inventories as a factor of production
3. stock-out avoidance
4. work in process

Goods not yet completed are counted in inventory.

## The Accelerator Model

A simple theory that explains the behavior of inventory investment, without endorsing any particular motive

## The Accelerator Model

- Notation:
$\mathbf{N}=$ stock of inventories
$\Delta \mathbf{N}=$ inventory investment
- Assume:

Firms hold a stock of inventories proportional to their output

$$
N=\beta Y,
$$

where $\beta$ is an exogenous parameter reflecting firms' desired stock of inventory as a proportion of output.

## The Accelerator Model

Result:
$\Delta N=\beta \Delta Y$
Inventory investment is proportional to the change in output.

- When output is rising, firms increase inventories.
- When output is falling, firms allow their inventories to run down.

## Evidence for the Accelerator Model

## Inventories and the real interest rate

- The opportunity cost of holding goods in inventory: the interest that could have been earned on the revenue from selling those goods.
- Hence, inventory investment depends on the real interest rate.
- Example:

High interest rates in the 1980s motivated many firms to adopt just-in-time production, which is designed to reduce inventories.

## Chapter Summary

1. All types of investment depend negatively on the real interest rate.
2. Things that shift the investment function:

- Technological improvements raise MPK and raise business fixed investment.
- Increase in population raises demand for, price of housing and raises residential investment.
- Economic policies (corporate income tax, investment tax credit) alter incentives to invest.

## Chapter Summary

3. Investment is the most volatile component of GDP over the business cycle.

- Fluctuations in employment affect the MPK and the incentive for business fixed investment.
- Fluctuations in income affect demand for, price of housing and the incentive for residential investment.
- Fluctuations in output affect planned \& unplanned inventory investment.
