Consumer's Surplus

Monetary Measures of Gains-to-Trade

- ◆ You can buy as much gasoline as you wish at \$1 per gallon once you enter the gasoline market.
- ◆ Q: What is the most you would pay to enter the market?

Monetary Measures of Gains-to-Trade

- ◆ **A: You would pay up to the dollar value of the gains-to-trade you would enjoy once in the market.**
- ◆ **How can such gains-to-trade be measured?**

Monetary Measures of Gains-to-Trade

- ◆ **Three such measures are:**
 - **Consumer's Surplus**
 - **Equivalent Variation, and**
 - **Compensating Variation.**
- ◆ **Only in one special circumstance do these three measures coincide.**

\$ Equivalent Utility Gains

- ◆ **Suppose gasoline can be bought only in lumps of one gallon.**
- ◆ **Use r_1 to denote the most a single consumer would pay for a 1st gallon -- call this her reservation price for the 1st gallon.**
- ◆ **r_1 is the dollar equivalent of the marginal utility of the 1st gallon.**

\$ Equivalent Utility Gains

- ◆ Now that she has one gallon, use r_2 to denote the most she would pay for a 2nd gallon -- this is her reservation price for the 2nd gallon.
- ◆ r_2 is the dollar equivalent of the marginal utility of the 2nd gallon.

\$ Equivalent Utility Gains

- ◆ **Generally, if she already has $n-1$ gallons of gasoline then r_n denotes the most she will pay for an n th gallon.**
- ◆ **r_n is the dollar equivalent of the marginal utility of the n th gallon.**

\$ Equivalent Utility Gains

- ◆ $r_1 + \dots + r_n$ will therefore be the dollar equivalent of the total change to utility from acquiring n gallons of gasoline at a price of \$0.
- ◆ So $r_1 + \dots + r_n - p_G n$ will be the dollar equivalent of the total change to utility from acquiring n gallons of gasoline at a price of $\$p_G$ each.

\$ Equivalent Utility Gains

- ◆ A plot of $r_1, r_2, \dots, r_n, \dots$ against n is a reservation-price curve. This is not quite the same as the consumer's demand curve for gasoline.

\$ Equivalent Utility Gains

\$ Equivalent Utility Gains

- ◆ **What is the monetary value of our consumer's gain-to-trading in the gasoline market at a price of $\$p_G$?**

\$ Equivalent Utility Gains

- ◆ The dollar equivalent net utility gain for the 1st gallon is $\$(r_1 - p_G)$
- ◆ and is $\$(r_2 - p_G)$ for the 2nd gallon,
- ◆ and so on, so the dollar value of the gain-to-trade is

$$\$(r_1 - p_G) + \$(r_2 - p_G) + \dots$$

for as long as $r_n - p_G > 0$.

\$ Equivalent Utility Gains

\$ Equivalent Utility Gains

\$ Equivalent Utility Gains

\$ Equivalent Utility Gains

- ◆ Now suppose that gasoline is sold in half-gallon units.
- ◆ $r_1, r_2, \dots, r_n, \dots$ denote the consumer's reservation prices for successive half-gallons of gasoline.
- ◆ Our consumer's new reservation price curve is

Gasoline

\$ Equivalent Utility Gains

- ◆ **Unfortunately, estimating a consumer's reservation-price curve is difficult,**
- ◆ **so, as an approximation, the reservation-price curve is replaced with the consumer's ordinary demand curve.**

Consumer's Surplus

- ◆ **A consumer's reservation-price curve is not quite the same as her ordinary demand curve. Why not?**
- ◆ **A reservation-price curve describes sequentially the values of successive single units of a commodity.**
- ◆ **An ordinary demand curve describes the most that would be paid for q units of a commodity purchased simultaneously.**

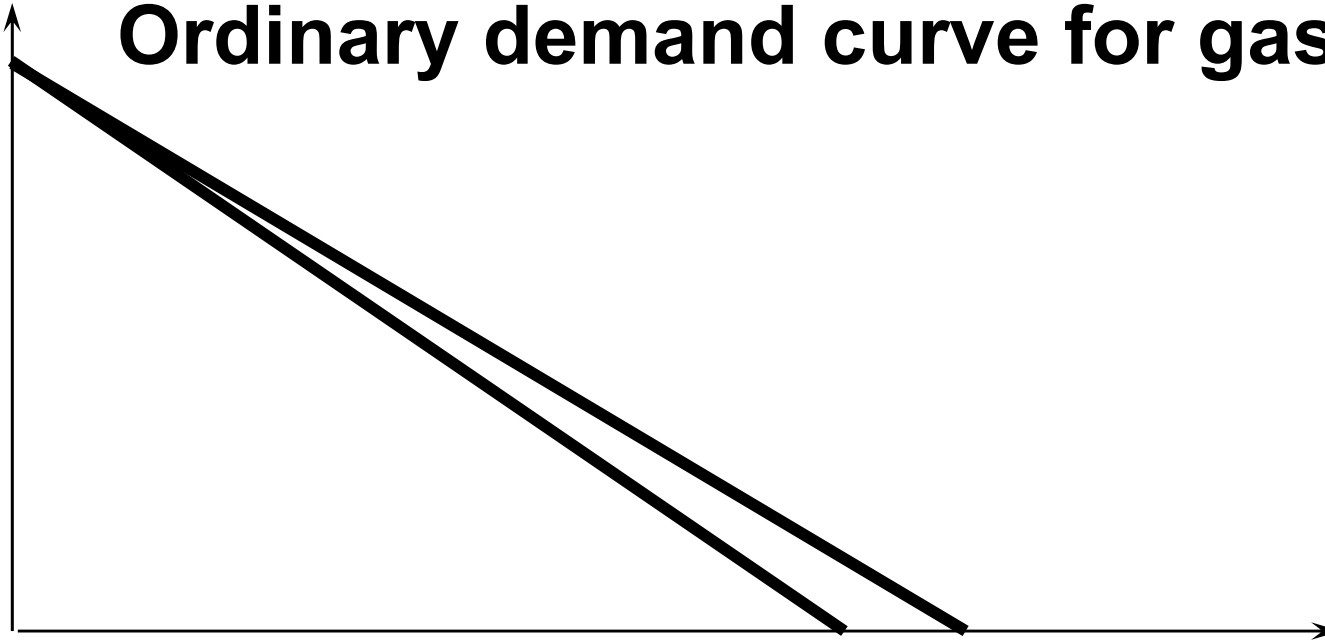

Consumer's Surplus

- ◆ **Approximating the net utility gain area under the reservation-price curve by the corresponding area under the ordinary demand curve gives the Consumer's Surplus measure of net utility gain.**

Consumer's Surplus

- ◆ **The difference between the consumer's reservation-price and ordinary demand curves is due to income effects.**
- ◆ **But, if the consumer's utility function is quasilinear in income then there are no income effects and Consumer's Surplus is an exact \$ measure of gains-to-trade.**

Consumer's Surplus

The consumer's utility function is quasilinear in x_2 .

$$U(x_1, x_2) = v(x_1) + x_2$$

Take $p_2 = 1$. Then the consumer's choice problem is to maximize

$$U(x_1, x_2) = v(x_1) + x_2$$

subject to

$$p_1 x_1 + x_2 = m.$$

Consumer's Surplus

The consumer's utility function is quasilinear in x_2 .

$$U(x_1, x_2) = v(x_1) + x_2$$

Take $p_2 = 1$. Then the consumer's choice problem is to maximize

$$U(x_1, x_2) = v(x_1) + x_2$$

subject to

$$p_1 x_1 + x_2 = m.$$

Consumer's Surplus

That is, choose x_1 to maximize

$$v(x_1) + m - p_1 x_1.$$

The first-order condition is

$$v'(x_1) - p_1 = 0$$

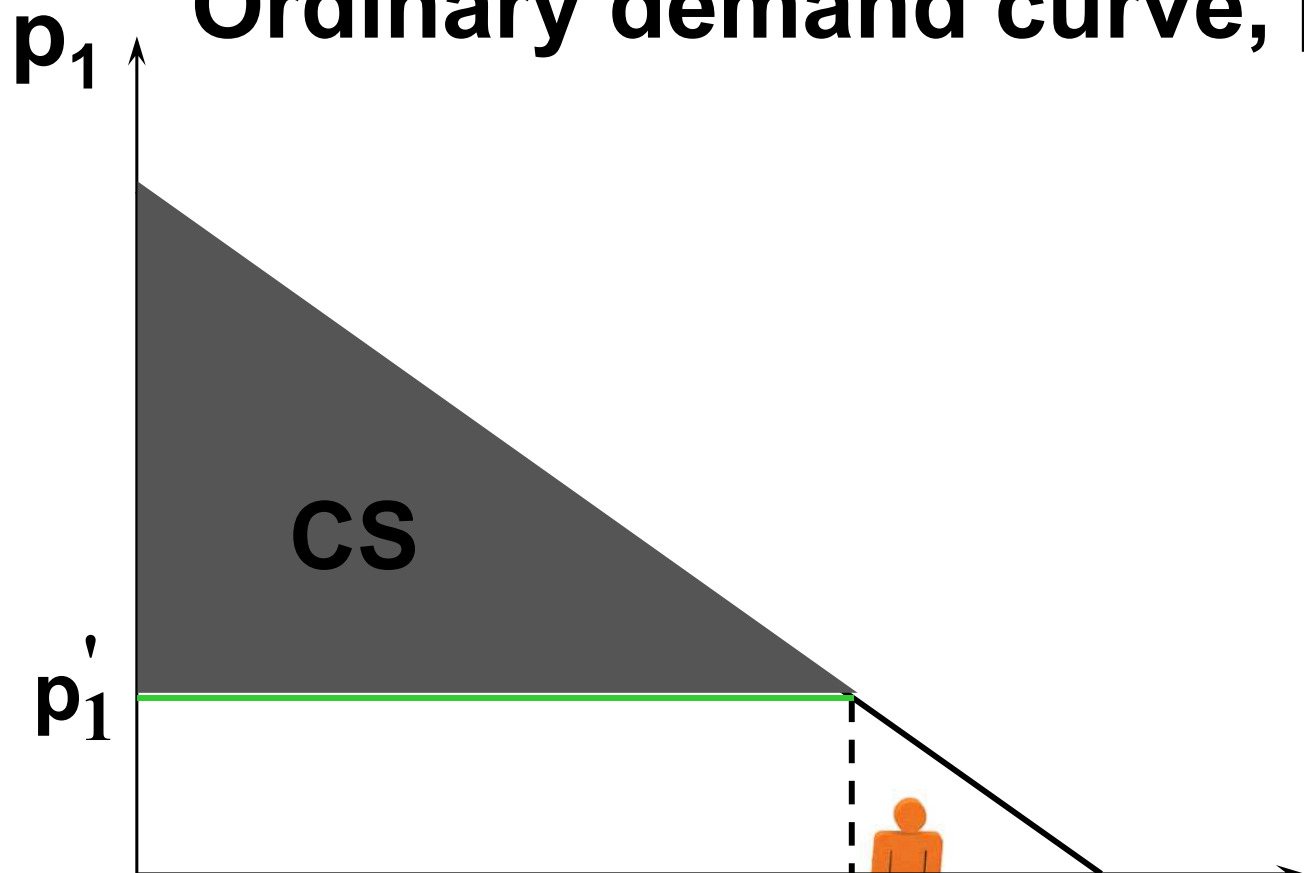

That is, $p_1 = v'(x_1)$.

This is the equation of the consumer's ordinary demand for commodity 1.

Consumer's Surplus

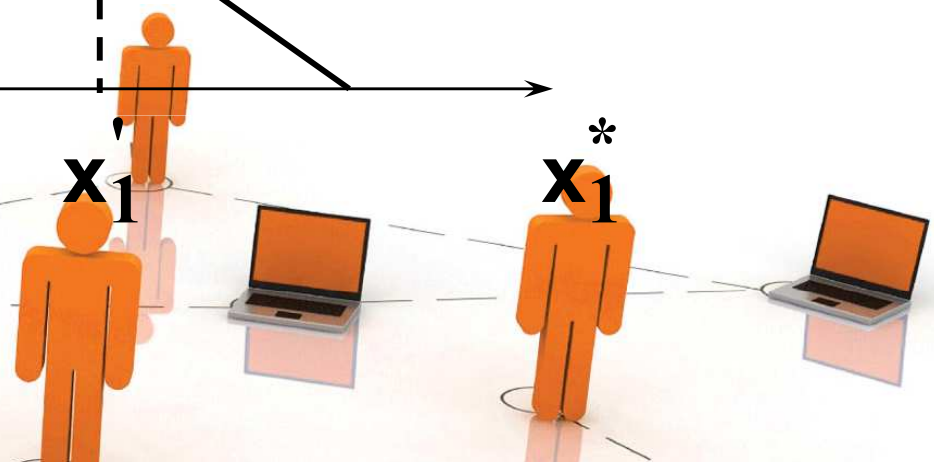

Ordinary demand curve, $p_1 = v'(x_1)$

Consumer's Surplus

Ordinary demand curve, $p_1 = v'(x_1)$

$$CS = \int_0^{x_1'} v'(x_1) dx_1 - p_1' x_1'$$

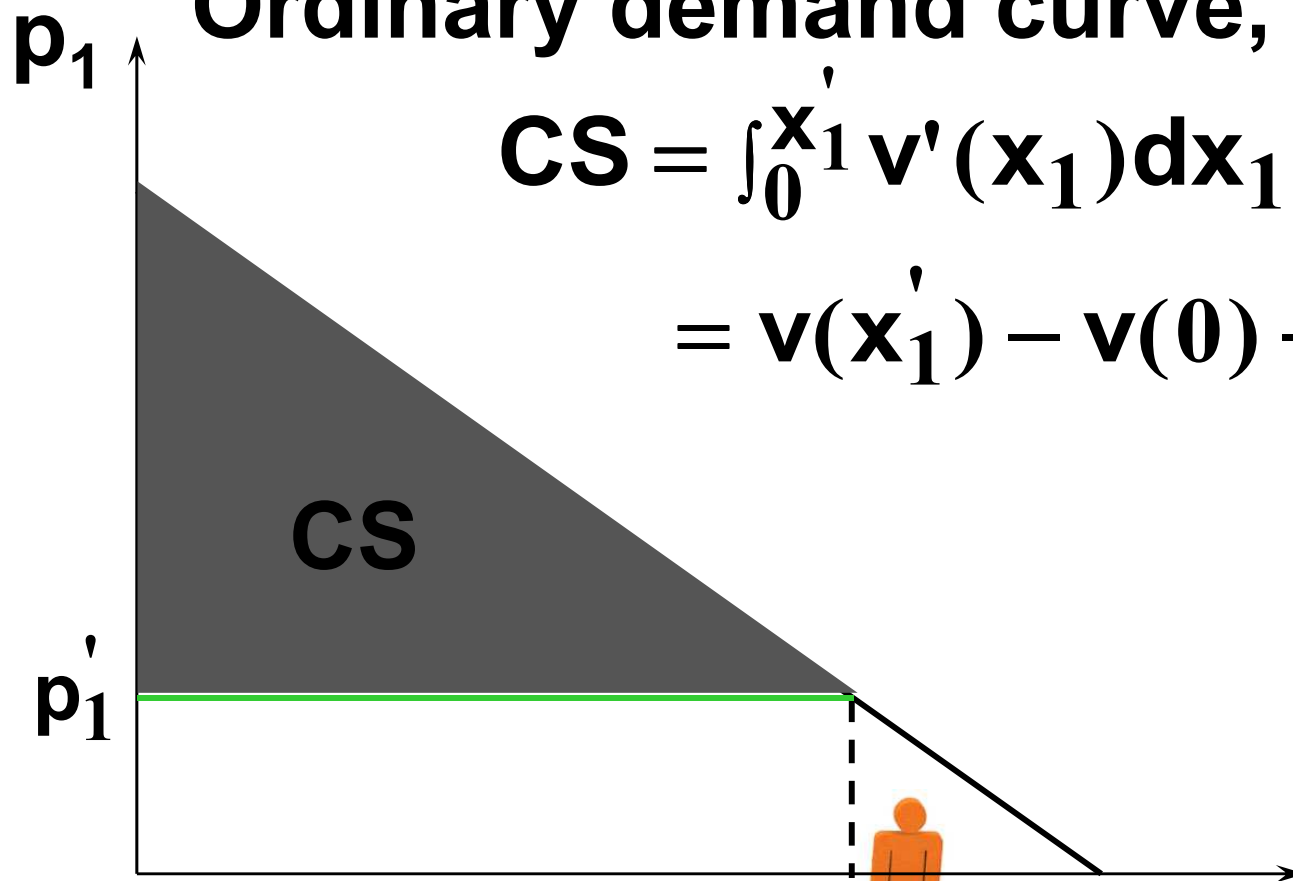

Consumer's Surplus

Ordinary demand curve, $p_1 = v'(x_1)$

$$CS = \int_0^{x_1'} v'(x_1) dx_1 - p_1' x_1'$$

$$= v(x_1') - v(0) - p_1' x_1'$$

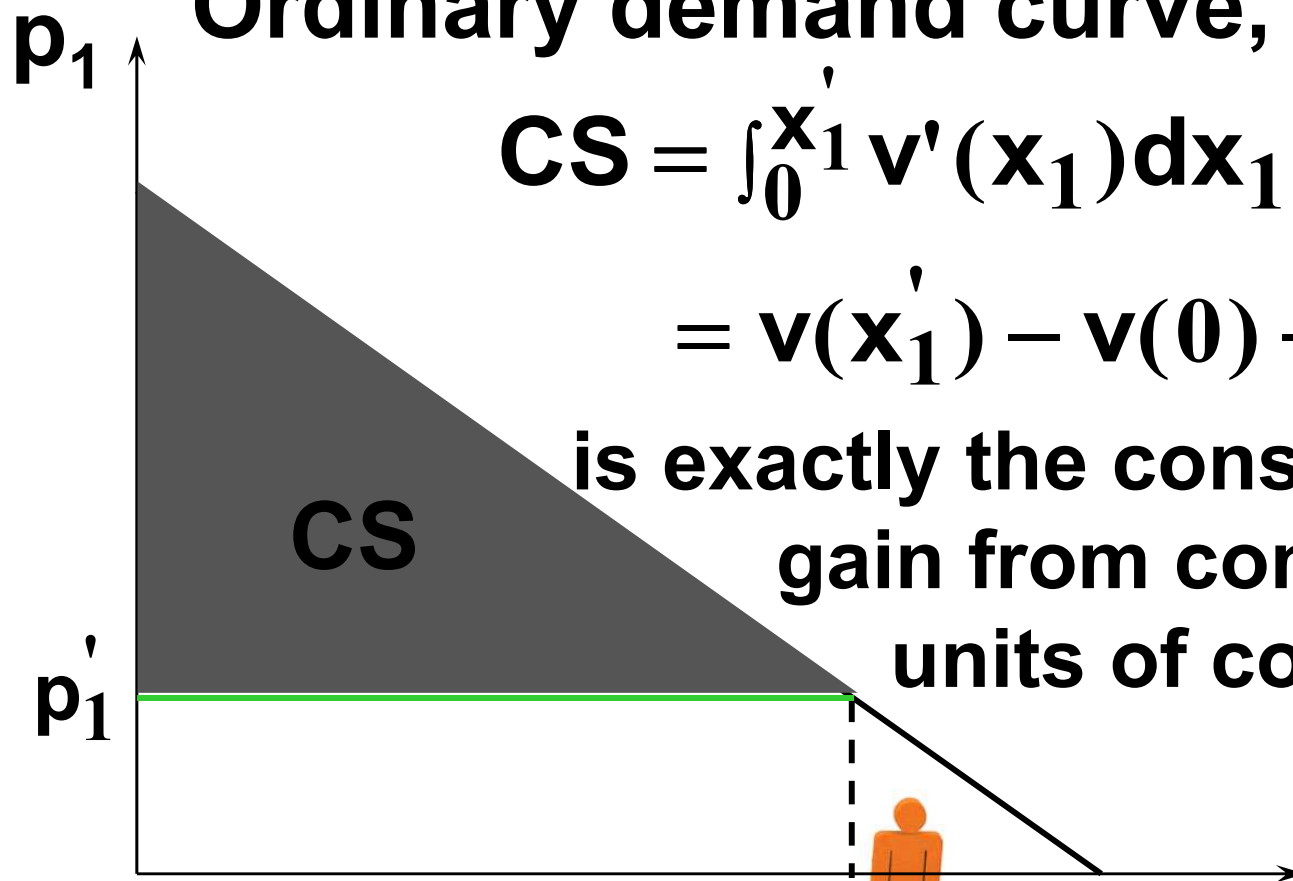

Consumer's Surplus

Ordinary demand curve, $p_1 = v'(x_1)$

$$CS = \int_0^{x_1'} v'(x_1) dx_1 - p_1' x_1'$$

$$= v(x_1') - v(0) - p_1' x_1'$$

is exactly the consumer's utility gain from consuming x_1' units of commodity 1.

Consumer's Surplus

- ◆ **Consumer's Surplus is an exact dollar measure of utility gained from consuming commodity 1 when the consumer's utility function is quasilinear in commodity 2.**
- ◆ **Otherwise Consumer's Surplus is an approximation.**

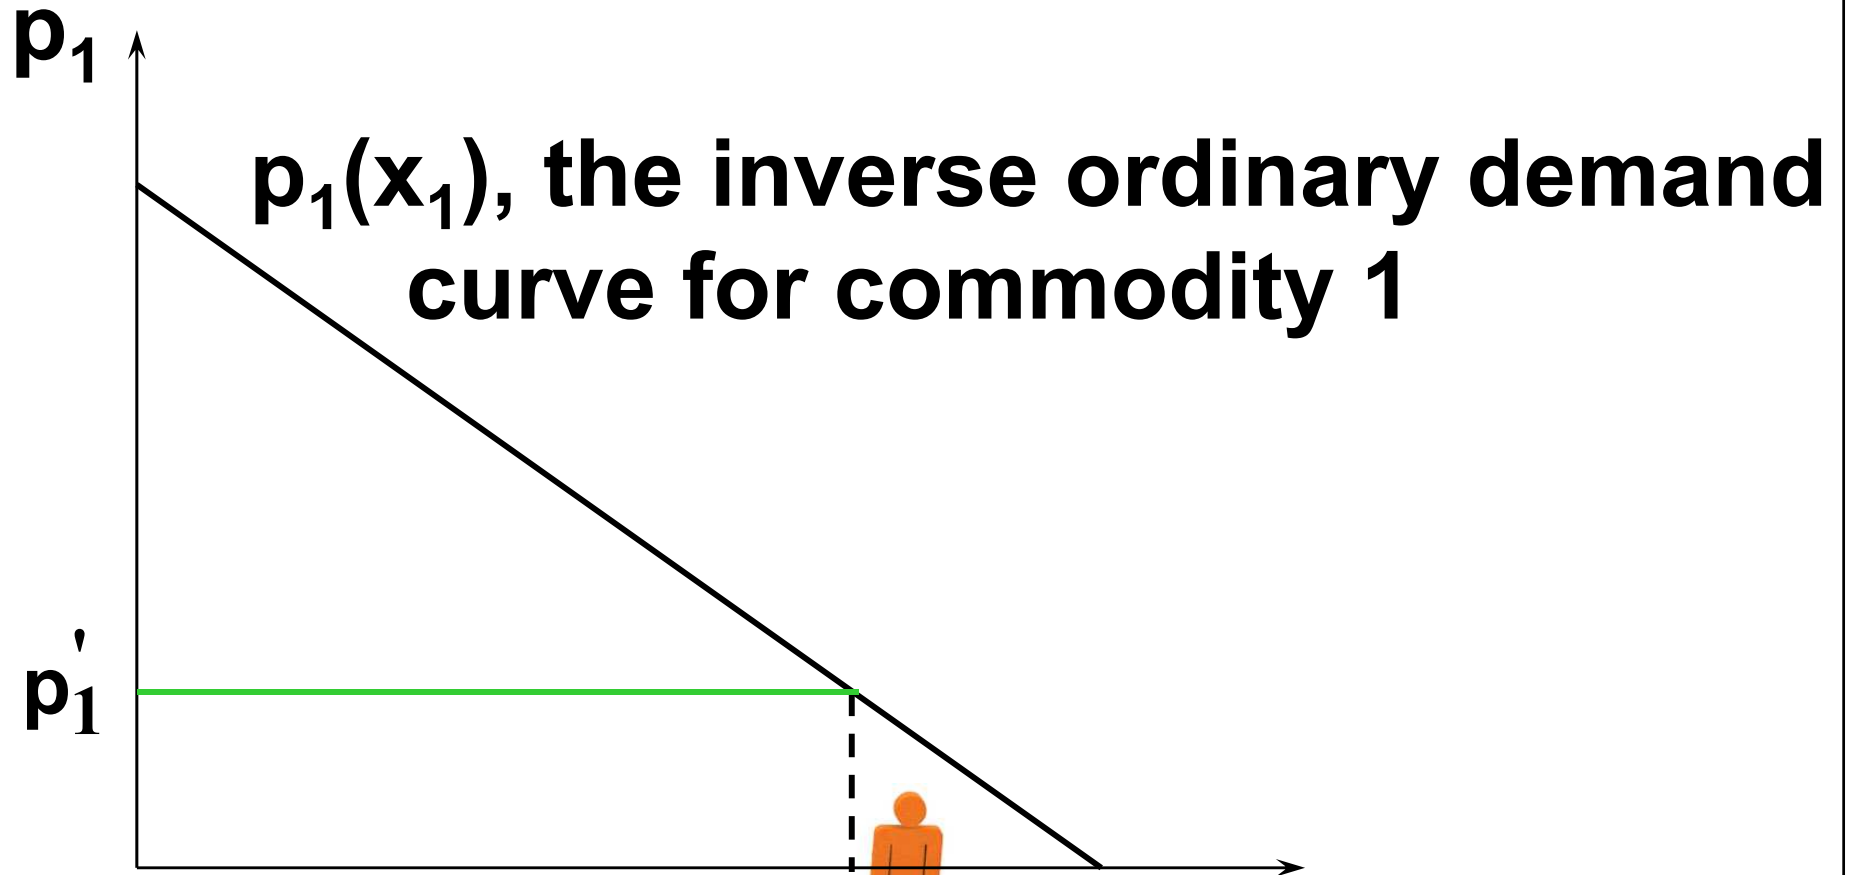

Consumer's Surplus

- ◆ **The change to a consumer's total utility due to a change to p_1 is approximately the change in her Consumer's Surplus.**

Consumer's Surplus

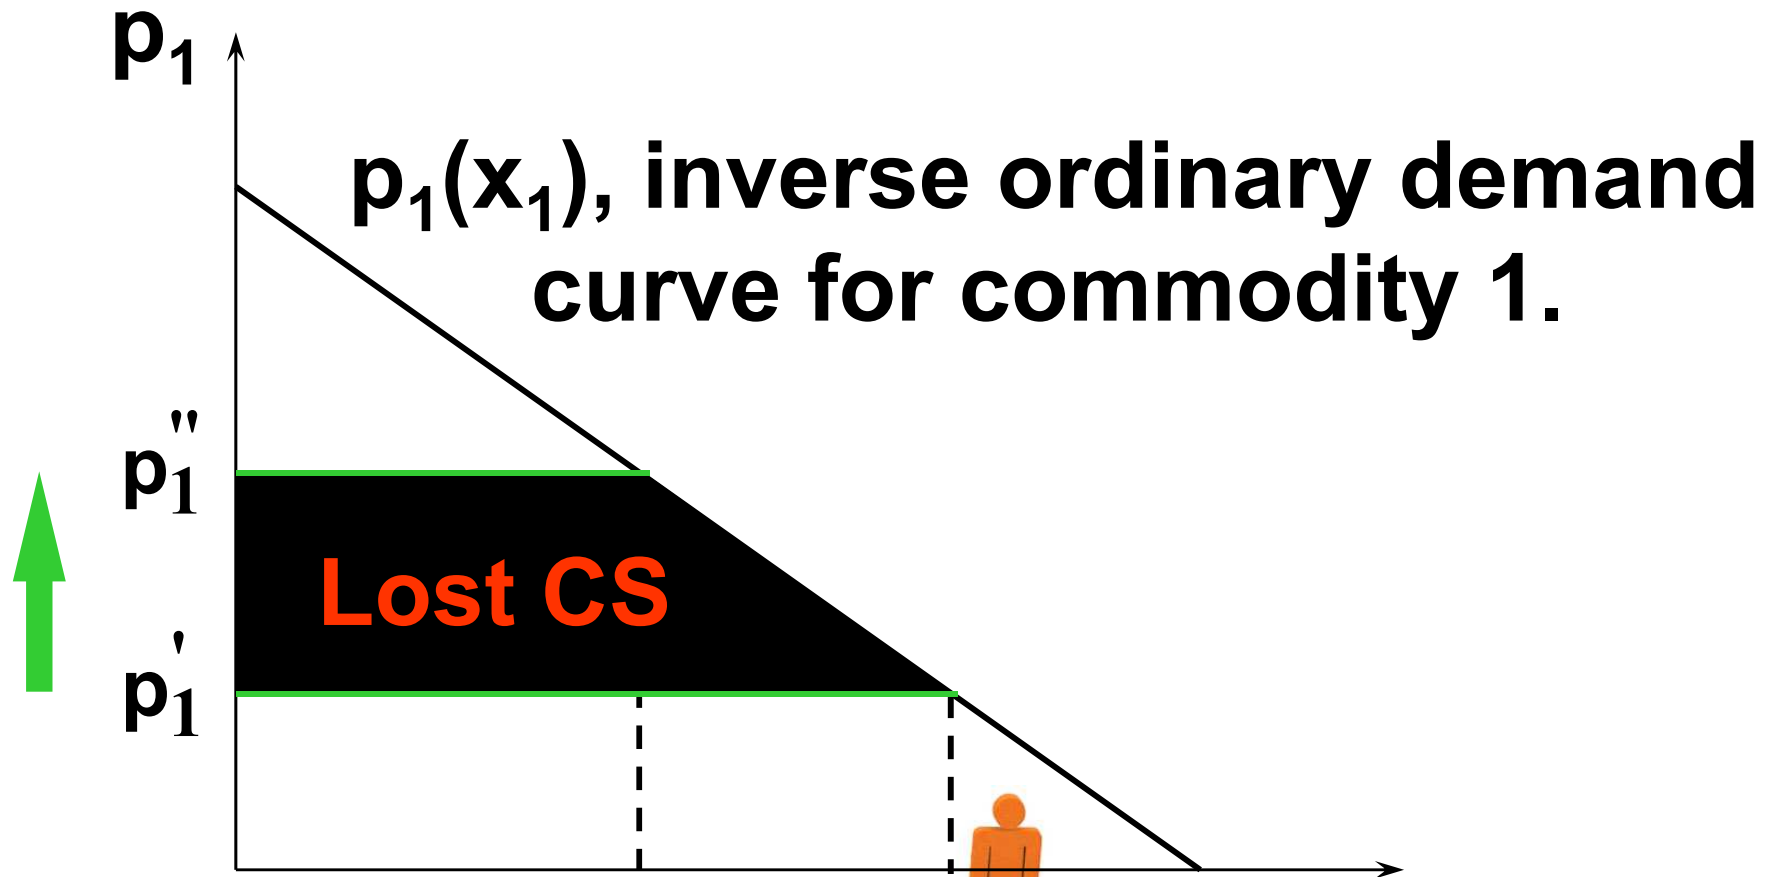

Consumer's Surplus

$x_1^*(p_1)$, the consumer's ordinary demand curve for commodity 1.

$$\Delta CS = \int_{p_1''}^{p_1'} x_1^*(p_1) dp_1$$

measures the loss in Consumer's Surplus.

Compensating Variation and Equivalent Variation

- ◆ **Two additional dollar measures of the total utility change caused by a price change are Compensating Variation and Equivalent Variation.**

Compensating Variation

- ◆ p_1 rises.
- ◆ Q: What is the least extra income that, at the new prices, just restores the consumer's original utility level?

Compensating Variation

- ◆ p_1 rises.
- ◆ **Q: What is the least extra income that, at the new prices, just restores the consumer's original utility level?**
- ◆ **A: The Compensating Variation.**

Compensating Variation

Compensating Variation

Compensating Variation

Compensating Variation

Equivalent Variation

- ◆ p_1 rises.
- ◆ Q: What is the least extra income that, at the original prices, just restores the consumer's original utility level?
- ◆ A: The Equivalent Variation.

Equivalent Variation

Equivalent Variation

Equivalent Variation

Equivalent Variation

Consumer's Surplus, Compensating Variation and Equivalent Variation

- ◆ **Relationship 1: When the consumer's preferences are quasilinear, all three measures are the same.**

Consumer's Surplus, Compensating Variation and Equivalent Variation

- ◆ Consider first the change in Consumer's Surplus when p_1 rises from p_1' to p_1'' .

Consumer's Surplus, Compensating Variation and Equivalent Variation

If $U(\mathbf{x}_1, \mathbf{x}_2) = v(\mathbf{x}_1) + \mathbf{x}_2$ then

$$CS(p'_1) = v(\mathbf{x}'_1) - v(\mathbf{0}) - p'_1 \mathbf{x}'_1$$

Consumer's Surplus, Compensating Variation and Equivalent Variation

If $U(\mathbf{x}_1, \mathbf{x}_2) = v(\mathbf{x}_1) + \mathbf{x}_2$ then

$$CS(p_1') = v(\mathbf{x}_1') - v(0) - p_1' \mathbf{x}_1'$$

and so the change in CS when p_1 rises from p_1' to p_1'' is

$$\Delta CS = CS(p_1') - CS(p_1'')$$

Consumer's Surplus, Compensating Variation and Equivalent Variation

If $U(\mathbf{x}_1, \mathbf{x}_2) = v(\mathbf{x}_1) + \mathbf{x}_2$ then

$$CS(p_1') = v(\mathbf{x}_1') - v(0) - p_1' \mathbf{x}_1'$$

and so the change in CS when p_1 rises from p_1' to p_1'' is

$$\Delta CS = CS(p_1') - CS(p_1'')$$

$$= v(\mathbf{x}_1') - v(0) - p_1' \mathbf{x}_1' - [v(\mathbf{x}_1'') - v(0) - p_1'' \mathbf{x}_1'']$$

Consumer's Surplus, Compensating Variation and Equivalent Variation

If $U(\mathbf{x}_1, \mathbf{x}_2) = v(\mathbf{x}_1) + \mathbf{x}_2$ then

$$CS(p_1') = v(\mathbf{x}_1') - v(0) - p_1' \mathbf{x}_1'$$

and so the change in CS when p_1 rises from p_1' to p_1'' is

$$\Delta CS = CS(p_1') - CS(p_1'')$$

$$= v(\mathbf{x}_1') - v(0) - p_1' \mathbf{x}_1' - [v(\mathbf{x}_1'') - v(0) - p_1'' \mathbf{x}_1'']$$

$$= v(\mathbf{x}_1') - v(\mathbf{x}_1'') - (p_1' \mathbf{x}_1' - p_1'' \mathbf{x}_1'')$$

Consumer's Surplus, Compensating Variation and Equivalent Variation

◆ Now consider the change in CV when p_1 rises from p_1' to p_1'' .

◆ The consumer's utility for given p_1 is

$$v(x_1^*(p_1)) + m - p_1 x_1^*(p_1)$$

and CV is the extra income which, at the new prices, makes the consumer's utility the same as at the old prices. That is, ...

Consumer's Surplus, Compensating Variation and Equivalent Variation

$$\begin{aligned} & v(\mathbf{x}'_1) + m - p'_1 \mathbf{x}'_1 \\ &= v(\mathbf{x}''_1) + m + \mathbf{CV} - p''_1 \mathbf{x}''_1. \end{aligned}$$

Consumer's Surplus, Compensating Variation and Equivalent Variation

$$\begin{aligned} & v(\mathbf{x}'_1) + m - \mathbf{p}'_1 \mathbf{x}'_1 \\ &= v(\mathbf{x}''_1) + m + \mathbf{CV} - \mathbf{p}''_1 \mathbf{x}''_1. \end{aligned}$$

So

$$\begin{aligned} \mathbf{CV} &= v(\mathbf{x}'_1) - v(\mathbf{x}''_1) - (\mathbf{p}'_1 \mathbf{x}'_1 - \mathbf{p}''_1 \mathbf{x}''_1) \\ &= \Delta \mathbf{CS}. \end{aligned}$$

Consumer's Surplus, Compensating Variation and Equivalent Variation

◆ Now consider the change in EV when p_1 rises from p_1' to p_1'' .

◆ The consumer's utility for given p_1 is

$$v(x_1^*(p_1)) + m - p_1 x_1^*(p_1)$$

and EV is the extra income which, at the old prices, makes the consumer's utility the same as at the new prices.

That is, ...

Consumer's Surplus, Compensating Variation and Equivalent Variation

$$\begin{aligned} & \mathbf{v}(\mathbf{x}'_1) + \mathbf{m} - \mathbf{p}'_1 \mathbf{x}'_1 \\ &= \mathbf{v}(\mathbf{x}''_1) + \mathbf{m} + \mathbf{EV} - \mathbf{p}''_1 \mathbf{x}''_1. \end{aligned}$$

Consumer's Surplus, Compensating Variation and Equivalent Variation

$$\begin{aligned} & \mathbf{v}(\mathbf{x}'_1) + \mathbf{m} - \mathbf{p}'_1 \mathbf{x}'_1 \\ &= \mathbf{v}(\mathbf{x}''_1) + \mathbf{m} + \mathbf{EV} - \mathbf{p}''_1 \mathbf{x}''_1. \end{aligned}$$

That is,

$$\begin{aligned} \mathbf{EV} &= \mathbf{v}(\mathbf{x}'_1) - \mathbf{v}(\mathbf{x}''_1) - (\mathbf{p}'_1 \mathbf{x}'_1 - \mathbf{p}''_1 \mathbf{x}''_1) \\ &= \Delta \mathbf{CS}. \end{aligned}$$

Consumer's Surplus, Compensating Variation and Equivalent Variation

So when the consumer has quasilinear utility,

$$CV = EV = \Delta CS.$$

But, otherwise, we have:

Relationship 2: In size, $EV < \Delta CS < CV$.

Producer's Surplus

- ◆ **Changes in a firm's welfare can be measured in dollars much as for a consumer.**
