Climate changes

Prof. RNDr. Milan Viturka, CSc. Ing. Paul Mark Ablorh FEPA MU, Brno

What is Global Warming?

<u>Global warming is the continued rise in the mean temperature of the Earth's climate</u> <u>system.</u>

This may be due to the continued rise in the average temperatures of air and

oceans as a result of the production of green house gases

What is Climate Change?

<u>Climate change includes global warming and its effect such as rise in sea level,</u> <u>decrease in mountain glaciers, rapid melting of ice in the Antartica and changes in</u> <u>the blooming periods of plants and flowers</u>

Evidence of Climate Change

Rise in Temperature: The earth's temperature has risen on the average by about 0.9 degrees since the last century due to a rise in carbon dioxide and other human emissions in to the atmosphere

Ocean Warming: There has been a rise in the ocean temperature of about 0.4degrees Decreasing Ice Sheet: There has been a reduction in the Antarctica ice mass by about a third.

Glacial Withdrawal:: There seems to be a withdrawal of glaciers in the Alps, Himalayas,

Andes, Rockies, Alaska and Africa

Snow Cover: snow cover in the Northern Hemisphere has reduced for the last 50years and that, snow there is melting sooner than expected

Sea Level: There are indications that sea level rose about 16 inches in the last two decades and this is expected to increase every year.

Extreme Events:heat waves, prolonged periods of high temperatures, heavy downpours, severe floods and droughts are some extreme events that are common place now Ocean Acidification: The acidity of ocean waters has increased by about 30 percent. due to the

The indicators for a global warming

Causes:

Global warming is due to the atmosphere trapping heat radiating from Earth toward space. The following gases are the main contributors to global warming: Water vapor(H₂0), Carbon dioxide (CO2), Methane(CH₄), Nitrous oxide(N₂O), Chlorofluorocarbons (CFCs).

Effects:

Uneven rise in temperature.

Increase in length of frost-free and growing season which can affect the ecosystem and agriculture

More rains, snow and heavy downpours due to increased precipitation

- Increased heat waves and drought
- Powerful hurricanes and storms
- Rising sea levels
- Possible ice-free Artic

What is Global Warming and Climate Change?

<u>Global warming refer to an increase in average global temperatures.</u> Natural events and human activities are believed to be contributing to an increase in average global temperatures. This is caused primarily by increases in "greenhouse " gases. <u>A warming planet thus leads to a change in climate which can affect weather in</u> various ways. What are the main indicators of Climate Change?

As explained by the US agency "National Oceanic and Atmospheric Administration," there are seven indicators that would be expected to increase in a warming world and three indicators would be expected to decrease:

Prediction of climate change

The Intergovernmental Panel on Climate Change predicts that temperatures are most likely to rise by 1,8 $^{\circ}$ C - 4 $^{\circ}$ C by 2100. But the possible range is much greater; 1,1 $^{\circ}$ C - 6,4 $^{\circ}$ C. The maps above show how a range of three different scenarios will affect different parts of the planet. The emissions scenarios, A1B, A2, B1, used to create the maps above, are based on a range of detailed economic and technological data. These versions of the future consider different population increases, fossil and alternative fuel use, and consequent CO₂ increases.

The term greenhouse is used in conjunction with the phenomenon known as the greenhouse effect

- > energy from the sun drives the earth's weather and climate, and heats the earth's surface
- in turn, the earth radiates energy back into space
- six main greenhouse gases and water vapour trap some of the outgoing energy, retaining heat somewhat like the glass panels of a greenhouse
- the result is the rise in temperature on Earth as certain gases in the atmosphere trap energy.
- six main greenhouse gases are: carbon dioxide/CO₂, methane/CH₄ (which is 20 times potent as CO₂) and nitrous oxide/N₂O plus three fluorinated industrial gases i. e. hydrofluorocarbons/HFCs, perfluorocarbons/PFCs) and sulphur hexafluoride/SF₆

This is a necessary sign that the greenhouse effect is a prerequisite for life on Earth - without their effect, the average temperature at the Earth's surface (determined only by the radiation balance) was -18 ° C.

Human impact on climate change

Human activity has caused an imbalance in the natural cycle of the greenhouse effect and related processes.

- when we mine coal and extract oil from the Earth's crust, and then burn these fossil fuels for transportation, heating, cooking, electricity and manufacturing, we are effectively moving carbon into the atmosphere than is being removed naturally through the sedimentation of carbon.
- by clearing forests to support agriculture, we are transferring carbon from living biomass into the atmosphere (dry wood is about 50 percent carbon).
- if the greenhouse effect becomes stronger, then more heat gets trapped than needed, and the Earth might become less habitable for humans, plants and animals.
- the difference between the natural carbon cycle and human-induced climate change is that the latter is rapid and ecosystems have less chance of adapting to the changes.

The result is that humans are adding ever-increasing amounts of extra carbon dioxide into the atmosphere. Because of this, atmospheric carbon dioxide concentrations are higher today than they have been over the last half-million years or longer.

Main indicators

Ecosystem Impacts

Many studies have pointed out that the rates of extinction of animal and plant species, and the temperature changes around the world since the industrial revolution have been significantly different to normal expectations.

Those observations note that global climate changes will lead to the following situations:

- rapid global warming
- dramatic increase in greenhouse gas emissions
- warming of the oceans leads to further increase greenhouse gasses
- permafrost thawing will aggravate global warming
- induced massive extinction of species deepens the environmental crisis
- such vicious circle where each problem exacerbate other problems can lead to a sudden collapse of biological and ecological systems
- effective measures can decrease global warming and other problems, unfortunately the world community has repeatedly failed to establish cooperation in this.

Other impacts

- rising sea levels affecting many small islands and a large mass of humanity lives near the coasts or by major rivers
- increasing ocean acidification resulting changes in the chemistry of the oceans disrupts the liveability of plants and animals in the sea
- increase in pests and disease climate changes can increase pathogen development, disease transmission and host susceptibility
- failing agricultural output, increase in world hunger drought and desertification are starting to spread and, intensify in some parts of the world already
- agriculture and livelihoods are already being affected most noticeably in the tropics and subtropics
- changing crops in some cases, improved agricultural techniques may help, such as rainwater harvesting and drip irrigation (some also believe may be essential to deal with changing climate).

The climate has always varied in the past. How is this any different?

Throughout Earth's history the climate has varied, sometimes considerably. Past warming does not automatically mean that today's warming is therefore also natural. Recent warming has been shown to be due to human industrialization processes.

Global atmospheric concentrations of carbon dioxide, methane and nitrous oxide have increased markedly as a result of human activities since 1750. The global increases in carbon dioxide concentration are due primarily to fossil fuel use and land-use change, while those of methane and nitrous oxide are primarily due to agriculture.

There is a huge contrast between developed and developing countries. In terms of historical emissions, industrialized countries account for roughly 80% of the carbon dioxide. Much of the growth in emissions in developing countries results from the provision of basic human needs for growing populations, while emissions in industrialized countries contribute to growth in a standard of living.

This is exemplified by the large contrasts in per capita carbons emissions between industrialized and developing countries (per capita emissions of carbon in the U.S. are over 20 times higher than India); around 2007, China surpassed the US as the world's largest emitter.

Development of emission of CO₂

At the 1997 Kyoto Conference, industrialized countries were committed to an overall reduction of emissions of greenhouse gases to 5.2% below 1990 levels for the period 2008—2012. The set targets were not met - overall global GHG emissions increased by 11% over the reference period.

Ozon depletion and extinction

The ongoing accumulation of greenhouse gasses causes increasing global warming.

- This causes a more extensive destruction of ozone in the polar regions because of accentuated stratospheric cooling.
- increase of ozone destruction increases the UV-radiation that, combined with higher ocean temperature, causes a reduction of the gigantic carbon dioxide trapping mechanism of the oceanic phytoplankton biomass;
- □ This accentuates the warming process.
- When the warming has reached a certain level, it will release huge amounts of greenhouse gasses trapped in the permafrost.
- This will enhance the global warming, and the polar destruction of ozone, and so on.

WATER STRESS BY COUNTRY

ratio of withdrawals to supply

Low stress (< 10%) Low to medium stress (10-20%) Medium to high stress (20-40%) High stress (40-80%) Extremely high stress (> 80%)

This map shows the average exposure of water users in each country to water stress, the ratio of total withdrawals to total renewable supply in a given area. A higher percentage means more water users are competing for limited supplies. Source: WRI Aqueduct, Gassert et al. 2013

Top 10 warmest years (1880-2014).

Rank 1 = warmest period of record	Year	Anomaly °C
1	2014	0.69
2 (tie)	2010	0.65
2 (tie)	2005	0.65
4	1998	0.63
5 (tie)	2013	0.62
5 (tie)	2003	0.62
7	2002	0.61
8	2006	0.60
9 (tie)	2009	0.59
9 (tie)	2007	0.59

For a very long time, something of contention and debate in the U.S. had been whether or not a lot of climate change has in fact been induced by human activities, while many scientists around the world, Europe especially, have been more convinced that this is the case.

Climate Consensus?

How many US scientists disagree with human-induced climate change?

David McCandless and Helen Lawson Williams // v2.0 // Dec 09 // [nformation[sBeautiful.net

Mark Twain might as well have been talking about global warming when he famously remarked, "Everybody talks about the weather, but nobody ever does anything about it." For years we have heard so much about the causes of climate change, that we've missed the fact that there are simple, practical solutions

that can slow this growing problem. Technologies exist today that can cut emissions of heat trapping gases and make a real difference in the health of our planet. And these solutions will be good for our economy, reduce our dependence

on foreign oil, and enhance our energy security.

Union of Concerned Scientist.

Challenge We Can Meet

Global warming doesn't just mean balmy February days in northern climes. It also means increasingly hot days in the summer, and a host of negative impacts that are already under way and are expected to intensify in the coming decades.

- □ More heat waves will likely increase the risk of heat-related illnesses and deaths.
- □ Cities and towns along the nation's major rivers will experience more severe and ;; frequent floodings.
- □ Some areas will likely experience more extensive and prolonged droughts.
- Some of our favorite coastal and low-lying vacation areas, such as parts of the Florida Keys, will be much less appealing as sea levels rise, dunes erode, and the areas become more vulnerable to coastal storms.
- Many families and businesses, who have made their living from fishing, farming, and tourism could lose their livelihoods, and others who love hunting, boating, skiing, birdwatching, and just relaxing near lakes, streams and wetlands will see some of their favorite places irretrievably changed.

Deforestation in the Brazilian Amazon, 1988-2007

Reduce fossil fuel use

Burning fossil fuels increases the levels of greenhouse gases in the atmosphere. There are two ways to reduce fossil fuel use: Use less energy, or use alternative energy sources like solar and wind power.

Plant trees

Plants take in carbon dioxide and release oxygen. They use carbon to build their own tissues and return some of it to the soil in a process called sequestration. Deforestation of rain forests is a large contributor to global warming, but planting new trees, an help to offset this. Reduce waste

The production of waste contributes to global warming both directly and indirectly. Decomposing waste produces methane and other greenhouse gases. Recycling metal, plastic, glass and paper lowers greenhouse gas emissions, since recycled items take far less energy . Conserve water

Cities consume significant amounts of energy when purifying and distributing water, which contributes to greenhouse gas emissions. Saving water reduces the amount of energy used.

Aral lake: situation in 1989 and 2014

How each of us can contribute to this

- saving electricity by using energy-efficient appliances and compact fluorescent light bulbs, as well as reducing gasoline use and buying green power from your electricity provider, if available.
- reducing your consumption patterns and reusing items whenever possible minimizes your carbon footprint, since fewer new items need to be made
- turn off water immediately whenever you're not using it, and repair or replace leaky faucets and toilets. In your yard, landscape with plants and grasses that require less water, and capture rainwater in barrels for irrigating.

THANK YOU
