Support Vector Machines

Mikhail Bilenko

Machine Learning Group Department of Computer Sciences University of Texas at Austin

Linear Separators

• Binary classification can be viewed as the task of separating classes in feature space:

Linear Separators

• Which of the linear separators is optimal?

Classification Margin

- Distance from example \mathbf{x}_i to the separator is $r = \frac{\mathbf{w}^T \mathbf{x}_i + b}{\|\mathbf{w}\|}$
- Examples closest to the hyperplane are *support vectors*.
- *Margin* ρ of the separator is the distance between support vectors.

Maximum Margin Classification

- Maximizing the margin is good according to intuition and PAC theory.
- Implies that only support vectors matter; other training examples are ignorable.

Linear SVM Mathematically

• Let training set $\{(\mathbf{x}_i, y_i)\}_{i=1..n}, \mathbf{x}_i \in \mathbb{R}^d, y_i \in \{-1, 1\}$ be separated by a hyperplane with margin ρ . Then for each training example (\mathbf{x}_i, y_i) :

$$\mathbf{w}^{\mathsf{T}}\mathbf{x}_{i} + b \leq -\rho/2 \quad \text{if } y_{i} = -1 \\ \mathbf{w}^{\mathsf{T}}\mathbf{x}_{i} + b \geq \rho/2 \quad \text{if } y_{i} = 1 \quad \Leftrightarrow \quad y_{i}(\mathbf{w}^{\mathsf{T}}\mathbf{x}_{i} + b) \geq \rho/2$$

- For every support vector \mathbf{x}_s the above inequality is an equality. After rescaling \mathbf{w} and b by $\rho/2$ in the equality, we obtain that distance between each \mathbf{x}_s and the hyperplane is $r = \frac{\mathbf{y}_s(\mathbf{w}^T\mathbf{x}_s + b)}{\|\mathbf{w}\|} = \frac{1}{\|\mathbf{w}\|}$
- Then the margin can be expressed through (rescaled) w and b as:

$$\rho = 2r = \frac{2}{\|\mathbf{w}\|}$$

Linear SVMs Mathematically (cont.)

• Then we can formulate the *quadratic optimization problem*:

Find w and b such that $\rho = \frac{2}{\|\mathbf{w}\|}$ is maximized and for all $(\mathbf{x}_i, y_i), i=1..n$: $y_i(\mathbf{w}^T\mathbf{x}_i + b) \ge 1$

Which can be reformulated as:

Find w and b such that

 $\Phi(\mathbf{w}) = ||\mathbf{w}||^2 = \mathbf{w}^T \mathbf{w}$ is minimized

and for all (\mathbf{x}_i, y_i) , $i=1..n: y_i (\mathbf{w}^T \mathbf{x}_i + b) \ge 1$

Solving the Optimization Problem

Find w and b such that $\Phi(\mathbf{w}) = \mathbf{w}^{\mathrm{T}}\mathbf{w}$ is minimized and for all $(\mathbf{x}_i, y_i), i=1..n$: $y_i (\mathbf{w}^{\mathrm{T}}\mathbf{x}_i + b) \ge 1$

- Need to optimize a *quadratic* function subject to *linear* constraints.
- Quadratic optimization problems are a well-known class of mathematical programming problems for which several (non-trivial) algorithms exist.
- The solution involves constructing a *dual problem* where a *Lagrange multiplier* α_i is associated with every inequality constraint in the primal (original) problem:

Find
$$\alpha_1 \dots \alpha_n$$
 such that
 $\mathbf{Q}(\mathbf{\alpha}) = \sum \alpha_i - \frac{1}{2} \sum \alpha_i \alpha_j y_i y_j \mathbf{x}_i^{\mathsf{T}} \mathbf{x}_j$ is maximized and
(1) $\sum \alpha_i y_i = 0$
(2) $\alpha_i \ge 0$ for all α_i

The Optimization Problem Solution

• Given a solution $\alpha_1 \dots \alpha_n$ to the dual problem, solution to the primal is:

$$\mathbf{w} = \sum \alpha_i y_i \mathbf{x}_i \qquad b = y_k - \sum \alpha_i y_i \mathbf{x}_i^{\mathsf{T}} \mathbf{x}_k \quad \text{for any } \alpha_k > 0$$

- Each non-zero α_i indicates that corresponding \mathbf{x}_i is a support vector.
- Then the classifying function is (note that we don't need w explicitly):

$$f(\mathbf{x}) = \sum \alpha_i y_i \mathbf{x}_i^{\mathrm{T}} \mathbf{x} + b$$

- Notice that it relies on an *inner product* between the test point x and the support vectors x_i we will return to this later.
- Also keep in mind that solving the optimization problem involved computing the inner products $\mathbf{x}_i^{T}\mathbf{x}_j$ between all training points.

Soft Margin Classification

- What if the training set is not linearly separable?
- Slack variables ξ_i can be added to allow misclassification of difficult or noisy examples, resulting margin called *soft*.

Soft Margin Classification Mathematically

• The old formulation:

Find w and b such that $\Phi(\mathbf{w}) = \mathbf{w}^{\mathrm{T}}\mathbf{w}$ is minimized and for all $(\mathbf{x}_i, y_i), i=1..n$: $y_i (\mathbf{w}^{\mathrm{T}}\mathbf{x}_i + b) \ge 1$

• Modified formulation incorporates slack variables:

Find w and b such that $\Phi(\mathbf{w}) = \mathbf{w}^{\mathrm{T}}\mathbf{w} + C\Sigma\xi_{i} \text{ is minimized}$ and for all $(\mathbf{x}_{i}, y_{i}), i=1..n: y_{i}(\mathbf{w}^{\mathrm{T}}\mathbf{x}_{i}+b) \ge 1-\xi_{i}, \xi_{i} \ge 0$

• Parameter *C* can be viewed as a way to control overfitting: it "trades off" the relative importance of maximizing the margin and fitting the training data.

Soft Margin Classification – Solution

• Dual problem is identical to separable case (would *not* be identical if the 2norm penalty for slack variables $C\Sigma \xi_i^2$ was used in primal objective, we would need additional Lagrange multipliers for slack variables):

Find
$$\alpha_1 \dots \alpha_N$$
 such that
 $\mathbf{Q}(\boldsymbol{\alpha}) = \sum \alpha_i - \frac{1}{2} \sum \alpha_i \alpha_j y_i y_j \mathbf{x}_i^T \mathbf{x}_j$ is maximized and
(1) $\sum \alpha_i y_i = 0$
(2) $0 \le \alpha_i \le C$ for all α_i

- Again, \mathbf{x}_i with non-zero α_i will be support vectors.
- Solution to the dual problem is:

 $\mathbf{w} = \sum \alpha_i y_i \mathbf{x}_i$ $b = y_k (1 - \xi_k) - \sum \alpha_i y_i \mathbf{x}_i^{\mathrm{T}} \mathbf{x}_k \quad \text{for any } k \text{ s.t. } \alpha_k > 0$ Again, we don't need to compute **w** explicitly for classification:

$$f(\mathbf{x}) = \sum \alpha_i y_i \mathbf{x}_i^{\mathsf{T}} \mathbf{x} + b$$

Theoretical Justification for Maximum Margins

• Vapnik has proved the following: The class of optimal linear separators has VC dimension h bounded from above as $h \le \min\left\{\left[\frac{D^2}{\rho^2}\right], m_0\right\} + 1$

where ρ is the margin, D is the diameter of the smallest sphere that can enclose all of the training examples, and m_0 is the dimensionality.

- Intuitively, this implies that regardless of dimensionality m_0 we can minimize the VC dimension by maximizing the margin ρ .
- Thus, complexity of the classifier is kept small regardless of dimensionality.

Linear SVMs: Overview

- The classifier is a *separating hyperplane*.
- Most "important" training points are support vectors; they define the hyperplane.
- Quadratic optimization algorithms can identify which training points \mathbf{x}_i are support vectors with non-zero Lagrangian multipliers α_i .
- Both in the dual formulation of the problem and in the solution training points appear only inside inner products:

Find $\alpha_1 \dots \alpha_N$ such that $\mathbf{Q}(\boldsymbol{\alpha}) = \sum \alpha_i - \frac{1}{2} \sum \alpha_i \alpha_j y_i y_j \mathbf{x}_i^{\mathsf{T}} \mathbf{x}_j$ is maximized and (1) $\sum \alpha_i y_i = 0$ (2) $0 \le \alpha_i \le C$ for all α_i

$$f(\mathbf{x}) = \sum \alpha_i \gamma_i \mathbf{x}_i^{\mathrm{T}} \mathbf{x} + b$$

Non-linear SVMs

• Datasets that are linearly separable with some noise work out great:

• But what are we going to do if the dataset is just too hard?

• How about... mapping data to a higher-dimensional space:

Non-linear SVMs: Feature spaces

• General idea: the original feature space can always be mapped to some higher-dimensional feature space where the training set is separable:

The "Kernel Trick"

- The linear classifier relies on inner product between vectors $K(\mathbf{x}_i, \mathbf{x}_j) = \mathbf{x}_i^T \mathbf{x}_j$
- If every datapoint is mapped into high-dimensional space via some transformation Φ : $\mathbf{x} \to \varphi(\mathbf{x})$, the inner product becomes:

$$K(\mathbf{x}_i, \mathbf{x}_j) = \boldsymbol{\varphi}(\mathbf{x}_i)^{\mathrm{T}} \boldsymbol{\varphi}(\mathbf{x}_j)$$

- A *kernel function* is a function that is equivalent to an inner product in some feature space.
- Example:

2-dimensional vectors $\mathbf{x} = [x_1 \ x_2]$; let $K(\mathbf{x}_i, \mathbf{x}_j) = (1 + \mathbf{x}_i^T \mathbf{x}_j)^2$, Need to show that $K(\mathbf{x}_i, \mathbf{x}_j) = \mathbf{\phi}(\mathbf{x}_i)^T \mathbf{\phi}(\mathbf{x}_j)$: $K(\mathbf{x}_i, \mathbf{x}_j) = (1 + \mathbf{x}_i^T \mathbf{x}_j)^2 = 1 + x_{i1}^2 x_{j1}^2 + 2 x_{i1} x_{j1} x_{i2} x_{j2} + x_{i2}^2 x_{j2}^2 + 2 x_{i1} x_{j1} + 2 x_{i2} x_{j2} = [1 \ x_{i1}^2 \ \sqrt{2} \ x_{i1} x_{i2} \ x_{i2}^2 \ \sqrt{2} x_{i1} \ \sqrt{2} x_{i2}]^T [1 \ x_{j1}^2 \ \sqrt{2} \ x_{j1} x_{j2} \ x_{j2}^2 \ \sqrt{2} x_{j1} \ \sqrt{2} x_{j2}] = \mathbf{\phi}(\mathbf{x}_i)^T \mathbf{\phi}(\mathbf{x}_j), \text{ where } \mathbf{\phi}(\mathbf{x}) = [1 \ x_1^2 \ \sqrt{2} \ x_1 x_2 \ x_2^2 \ \sqrt{2} x_1 \ \sqrt{2} x_2]$

• Thus, a kernel function *implicitly* maps data to a high-dimensional space (without the need to compute each $\varphi(\mathbf{x})$ explicitly).

What Functions are Kernels?

- For some functions $K(\mathbf{x}_i, \mathbf{x}_j)$ checking that $K(\mathbf{x}_i, \mathbf{x}_j) = \varphi(\mathbf{x}_i)^T \varphi(\mathbf{x}_j)$ can be cumbersome.
- Mercer's theorem:

Every semi-positive definite symmetric function is a kernel

• Semi-positive definite symmetric functions correspond to a semi-positive definite symmetric Gram matrix:

	$K(\mathbf{x}_1,\mathbf{x}_1)$	$K(\mathbf{x}_1,\mathbf{x}_2)$	$K(\mathbf{x}_1,\mathbf{x}_3)$	 $K(\mathbf{x}_1,\mathbf{x}_n)$
K=	$K(\mathbf{x}_2,\mathbf{x}_1)$	$K(\mathbf{x}_2,\mathbf{x}_2)$	$K(\mathbf{x}_2,\mathbf{x}_3)$	$K(\mathbf{x}_2,\mathbf{x}_n)$
	$K(\mathbf{x}_n,\mathbf{x}_1)$	$K(\mathbf{x}_n,\mathbf{x}_2)$	$K(\mathbf{x}_n,\mathbf{x}_3)$	 $K(\mathbf{x}_n,\mathbf{x}_n)$

Examples of Kernel Functions

- Linear: $K(\mathbf{x}_i, \mathbf{x}_i) = \mathbf{x}_i^T \mathbf{x}_i$
 - Mapping Φ : $\mathbf{x} \to \boldsymbol{\phi}(\mathbf{x})$, where $\boldsymbol{\phi}(\mathbf{x})$ is \mathbf{x} itself
- Polynomial of power $p: K(\mathbf{x}_i, \mathbf{x}_j) = (1 + \mathbf{x}_i^T \mathbf{x}_j)^p$ Mapping $\Phi: \mathbf{x} \to \boldsymbol{\varphi}(\mathbf{x})$, where $\boldsymbol{\varphi}(\mathbf{x})$ has $\binom{d+p}{p}$ dimensions

$$e^{-\frac{\left\|\mathbf{x}_{i}-\mathbf{x}_{j}\right\|^{2}}{2\sigma^{2}}}$$

- Gaussian (radial-basis function): $K(\mathbf{x}_i, \mathbf{x}_i) = 0$
 - Mapping $\Phi: \mathbf{x} \to \boldsymbol{\varphi}(\mathbf{x})$, where $\boldsymbol{\varphi}(\mathbf{x})$ is *infinite-dimensional*: every point is mapped to a function (a Gaussian); combination of functions for support vectors is the separator.
- Higher-dimensional space still has *intrinsic* dimensionality d (the mapping is not *onto*), but linear separators in it correspond to *non-linear* separators in original space.

Non-linear SVMs Mathematically

• Dual problem formulation:

Find $\alpha_1 \dots \alpha_n$ such that $\mathbf{Q}(\boldsymbol{\alpha}) = \sum \alpha_i - \frac{1}{2} \sum \alpha_i \alpha_j y_i y_j K(\mathbf{x}_i, \mathbf{x}_j)$ is maximized and (1) $\sum \alpha_i y_i = 0$ (2) $\alpha_i \ge 0$ for all α_i

• The solution is:

 $f(\mathbf{x}) = \sum \alpha_i y_i K(\mathbf{x}_i, \mathbf{x}_j) + b$

• Optimization techniques for finding α_i 's remain the same!

SVM applications

- SVMs were originally proposed by Boser, Guyon and Vapnik in 1992 and gained increasing popularity in late 1990s.
- SVMs are currently among the best performers for a number of classification tasks ranging from text to genomic data.
- SVMs can be applied to complex data types beyond feature vectors (e.g. graphs, sequences, relational data) by designing kernel functions for such data.
- SVM techniques have been extended to a number of tasks such as regression [Vapnik *et al.* '97], principal component analysis [Schölkopf *et al.* '99], etc.
- Most popular optimization algorithms for SVMs use *decomposition* to hillclimb over a subset of α_i 's at a time, e.g. SMO [Platt '99] and [Joachims '99]
- Tuning SVMs remains a black art: selecting a specific kernel and parameters is usually done in a try-and-see manner.
