### IA159 Formal Verification Methods LTL Model Checking of Pushdown Systems

#### Jan Strejček

Faculty of Informatics Masaryk University

#### Focus

- pushdown systems
- representation of sets of configurations
- computing all predecessors: checking safety properties
- state-based LTL model checking

#### Sources

- J. Esparza, D. Hansel, P. Rossmanith, and S. Schwoon: *Efficient algorithms for model checking pushdown systems*, CAV 2000, LNCS 1855, Springer, 2000.
- S. Schwoon: *Model-Checking Pushdown Systems*, PhD thesis, TUM, 2002.

Pushdown systems can be used to precisely model sequential programs with procedure calls, recursion, and both local and global variables.

A pushdown system is a triple  $\mathcal{P} = (P, \Gamma, \Delta)$ , where

- P is a finite set of control locations,
- Γ is a finite stack alphabet,
- $\Delta \subseteq (P \times \Gamma) \times (P \times \Gamma^*)$  is a finite set of transition rules.

We write  $\langle q, \gamma \rangle \hookrightarrow \langle q', w \rangle$  instead of  $((q, \gamma), (q', w)) \in \Delta$ .

We do not consider any input alphabet as we do not use pushdown systems as language acceptors.

# Definitions

- a configuration of *P* is a pair ⟨*p*, *w*⟩ ∈ *P* × Γ\*, where *w* is a stack content (the topmost symbol is on the left)
- the set of all configurations is denoted by C
- an immediate successor relation on configurations is defined in standard way
- reachability relation ⇒ ⊆ C × C is the reflexive and transitive closure of the immediate successor relation
- $\stackrel{+}{\Rightarrow} \subseteq C \times C$  is the transitive closure of the immediate successor relation
- given a set C ⊆ C of configurations, we define the set of their predecessors as

$$pre^*(C) = \{c \in C \mid \exists c' \in C . c \Rightarrow c'\}$$

 $\mathcal{P} ext{-automata}$ 

are finite automata used to represent sets of configurations

- use Γ as an alphabet
- have one initial state for every control location of the pushdown (we use P as the set of initial states)

Given a pushdown system  $\mathcal{P} = (P, \Gamma, \Delta)$ , a  $\mathcal{P}$ -automaton (or simply automaton) is a tuple  $\mathcal{A} = (Q, \Gamma, \delta, P, F)$  where

- Q is a finite set of states such that  $P \subseteq Q$ ,
- $\delta \subseteq \mathbf{Q} \times \mathbf{\Gamma} \times \mathbf{Q}$  is a set of transitions,
- $F \subseteq Q$  is a set of final states.

■ a (reflexive and transitive) transition relation  $\rightarrow \subseteq Q \times \Gamma^* \times Q$  is defined in a standard way

P-automaton A represents the set of configurations

$$Conf(\mathcal{A}) = \{ \langle p, w \rangle \mid \exists q \in F . p \xrightarrow{w} q \}$$

a set of configurations of *P* is called regular if it is recognized by some *P*-automaton In the rest of this section, we use

- p, p', p'', ... to denote initial states of an automaton (i.e. elements of P)
- **s**, s', s'', ... to denote non-initial states, and
- $q, q', q'', \dots$  to denote arbitrary states (initial or not).

## Verification of pushdown systems: the first step

### Computing $pre^*(C)$ for a regular set C

IA159 Formal Verification Methods: LTL Model Checking of Pushdown Systems

- Given a pushdown system *P* and a regular set of configurations *C*, the set *pre*<sup>\*</sup>(*C*) is again regular.
- 2 If *C* is defined by a  $\mathcal{P}$ -automaton  $\mathcal{A}$ , then the automaton  $\mathcal{A}_{pre^*}$  representing  $pre^*(C)$  is effectively constructible.

Intuition

$$\begin{array}{l} \langle \boldsymbol{p}_1, \gamma_0 \rangle \hookrightarrow \langle \boldsymbol{p}_2, \gamma_1 \gamma_2 \rangle \\ \langle \boldsymbol{p}_3, \gamma_3 \rangle \hookrightarrow \langle \boldsymbol{p}_1, \gamma_0 \gamma_1 \rangle \end{array}$$

 $\begin{array}{c} \langle \boldsymbol{p}_1, \gamma_0 \rangle \hookrightarrow \langle \boldsymbol{p}_2, \gamma_1 \gamma_2 \rangle \\ \langle \boldsymbol{p}_3, \gamma_3 \rangle \hookrightarrow \langle \boldsymbol{p}_1, \gamma_0 \gamma_1 \rangle \end{array}$ 

Intuition

 $\begin{array}{l} \langle \boldsymbol{\rho}_1, \gamma_0 \rangle \hookrightarrow \langle \boldsymbol{\rho}_2, \gamma_1 \gamma_2 \rangle \\ \langle \boldsymbol{\rho}_3, \gamma_3 \rangle \hookrightarrow \langle \boldsymbol{\rho}_1, \gamma_0 \gamma_1 \rangle \end{array}$ 

Let  $\mathcal{P}$  be a pushdown system and  $\mathcal{A}$  be a  $\mathcal{P}$ -automaton. We assume (w.l.o.g.) that  $\mathcal{A}$  has no transition leading to an initial state. The automaton  $\mathcal{A}_{pre^*}$  is obtained from  $\mathcal{A}$  by addition of new transitions according to the following rule:

#### Saturation rule

If  $\langle p, \gamma \rangle \hookrightarrow \langle p', w \rangle$  and  $p' \xrightarrow{w} q$  in the current automaton, add a transition  $(p, \gamma, q)$ .

- we apply this rule repeatedly until we reach a fixpoint
- a fixpoint exists as the number of possible new transitions is finite
- the resulting  $\mathcal{P}$ -automaton is  $\mathcal{A}_{pre^*}$

transition rules of  $\mathcal{P}$ :

$$\begin{array}{ll} \langle \boldsymbol{p}_{0}, \gamma_{0} \rangle \hookrightarrow \langle \boldsymbol{p}_{1}, \gamma_{1} \gamma_{0} \rangle & \langle \boldsymbol{p}_{2}, \gamma_{2} \rangle \hookrightarrow \langle \boldsymbol{p}_{0}, \gamma_{1} \rangle \\ \langle \boldsymbol{p}_{1}, \gamma_{1} \rangle \hookrightarrow \langle \boldsymbol{p}_{2}, \gamma_{2} \gamma_{0} \rangle & \langle \boldsymbol{p}_{0}, \gamma_{1} \rangle \hookrightarrow \langle \boldsymbol{p}_{0}, \varepsilon \rangle \end{array}$$

transition rules of  $\mathcal{P}$ :

$$\begin{array}{ll} \langle \boldsymbol{p}_{0}, \gamma_{0} \rangle \hookrightarrow \langle \boldsymbol{p}_{1}, \gamma_{1} \gamma_{0} \rangle & \langle \boldsymbol{p}_{2}, \gamma_{2} \rangle \hookrightarrow \langle \boldsymbol{p}_{0}, \gamma_{1} \rangle \\ \langle \boldsymbol{p}_{1}, \gamma_{1} \rangle \hookrightarrow \langle \boldsymbol{p}_{2}, \gamma_{2} \gamma_{0} \rangle & \langle \boldsymbol{p}_{0}, \gamma_{1} \rangle \hookrightarrow \langle \boldsymbol{p}_{0}, \varepsilon \rangle \end{array}$$

IA159 Formal Verification Methods: LTL Model Checking of Pushdown Systems

A pushdown system is in normal form if every rule  $\langle p, \gamma \rangle \hookrightarrow \langle p', w \rangle$  satisfies  $|w| \le 2$ .

Any pushdown system can be transformed into normal form with only linear size increase.

# Algorithm: notes

We give an algorithm that, for a given A, computes transitions of  $A_{pre^*}$ . The rest of the automaton  $A_{pre^*}$  is identical to A.

The algorithm uses sets *rel* and *trans* containing the transitions that are known to belong to  $A_{pre^*}$ :

- rel contains transitions that have already been examined
- no transition is examined more than once
- when we have a rule  $\langle p, \gamma \rangle \hookrightarrow \langle p', \gamma' \gamma'' \rangle$  and transitions  $t_1 = (p', \gamma', q')$  and  $t_2 = (q', \gamma'', q'')$  (where q, q' are arbitrary states), we have to add transition  $(p, \gamma, q'')$
- we do it in such a way that whenever we examine *t*<sub>1</sub>, we check if there is a corresponding *t*<sub>2</sub> ∈ *rel* and we add an extra rule ⟨*p*, *γ*⟩ → ⟨*q*′, *γ*″⟩ to a set of such extra rules Δ′
- the extra rule guarantees that if a suitable t<sub>2</sub> will be examined in the future, (p, γ, q") will be added.

# Algorithm

Input: a pushdown system  $\mathcal{P} = (P, \Gamma, \Delta)$  in normal form a  $\mathcal{P}$ -automaton  $\mathcal{A}=(Q, \Gamma, \delta, P, F)$  without transitions into POutput: the set of transitions of  $\mathcal{A}_{pre^*}$ 

1 rel :=  $\emptyset$ : trans :=  $\delta$ :  $\Delta'$  :=  $\emptyset$ : forall  $\langle p, \gamma \rangle \hookrightarrow \langle p', \varepsilon \rangle \in \Delta$  do trans := trans  $\cup \{(p, \gamma, p')\};$ 2 3 while trans  $\neq \emptyset$  do 4 pop  $t = (q, \gamma, q')$  from *trans*; 5 if  $t \notin rel$  then 6  $rel := rel \cup \{t\};$ 7 forall  $\langle p_1, \gamma_1 \rangle \hookrightarrow \langle q, \gamma \rangle \in (\Delta \cup \Delta')$  do 8 trans := trans  $\cup \{(p_1, \gamma_1, q')\};$ 9 forall  $\langle p_1, \gamma_1 \rangle \hookrightarrow \langle q, \gamma \gamma_2 \rangle \in \Delta$  do  $\Delta' := \Delta' \cup \{ \langle \boldsymbol{p}_1, \gamma_1 \rangle \hookrightarrow \langle \boldsymbol{q}', \gamma_2 \rangle \};$ 10 forall  $(q', \gamma_2, q'') \in rel$  do 11 12 trans := trans  $\cup \{(p_1, \gamma_1, q'')\}$ ; 13 return rel

IA159 Formal Verification Methods: LTL Model Checking of Pushdown Systems

#### Theorem

Let  $\mathcal{P} = (P, \Gamma, \Delta)$  be a pushdown system and  $\mathcal{A} = (Q, \Gamma, \delta, P, F)$ be a  $\mathcal{P}$ -automaton. There exists an automaton  $\mathcal{A}_{pre^*}$ recognizing pre\*(Conf( $\mathcal{A}$ )). Moreover,  $\mathcal{A}_{pre^*}$  can be constructed in  $\mathcal{O}(|Q|^2 \cdot |\Delta|)$  time and  $\mathcal{O}(|Q| \cdot |\Delta| + |\delta|)$  space.

- We can assume that every transition is added to *trans* at most once. This can be done (without asymptotic loss of time) by storing all transitions which are ever added to *trans* in an additional hash table.
- Further, we assume that there is at least one rule in Δ for every γ ∈ Γ (transitions of A under some γ not satisfying this assumption can be moved directly to *rel*).
- The number of transitions in δ as well as the number of iterations of the while-loop is bounded by |Q|<sup>2</sup> ⋅ |Δ|.

- Line 10 is executed for each combination of a rule  $\langle p_1, \gamma_1 \rangle \hookrightarrow \langle q, \gamma \gamma_2 \rangle$  and a transition  $(q, \gamma, q') \in trans$ , i.e. at most  $|Q| \cdot |\Delta|$  times.
- Hence,  $|\Delta'| \leq |Q| \cdot |\Delta|$ .
- For the loop starting at line 11, q' and y<sub>2</sub> are fixed. Thus, line 12 is executed at most |Q|<sup>2</sup> · |∆| times.
- Line 8 is executed for each combination of a rule  $\langle p_1, \gamma_1 \rangle \hookrightarrow \langle q, \gamma \rangle \in (\Delta \cup \Delta')$  and a transition  $(q, \gamma, q') \in trans$ . As  $|\Delta'| \leq |Q| \cdot |\Delta|$ , line 8 is executed at most  $\mathcal{O}(|Q|^2 \cdot |\Delta|)$  times.

As a conclusion, the algorithm takes  $\mathcal{O}(|Q|^2 \cdot |\Delta|)$  time.

Memory is needed for storing *rel*, *trans*, and  $\Delta'$ .

- The size of  $\Delta'$  is in  $\mathcal{O}(|Q| \cdot |\Delta|)$ .
- **Line 1** adds  $|\delta|$  transitions to *trans*.
- Line 2 adds at most  $|\Delta|$  transitions to *trans*.
- In lines 8 and 12, p<sub>1</sub> and γ<sub>1</sub> are given by the head of a rule in Δ (note that every rule in Δ' have the same head as some rule in Δ). Hence, lines 8 and 12 add at most |Q| · |Δ| different transitions.

We directly get that the algorithm needs  $\mathcal{O}(|Q| \cdot |\Delta| + |\delta|)$  space. As this is also the size of the result *rel*, the algorithm is optimal with respect to the memory usage.

### Notes

- the algorithm can be used to verify safety property: given an automaton A representing error configurations, we can compute A<sub>pre\*</sub>, i.e. the set of all configurations from which an error configuration is reachable
- there is a similar algorithm computing, for a given regular set of configurations C, the set of all successors

$$post^*(C) = \{c' \in C \mid \exists c \in C . c \Rightarrow c'\}$$

#### Theorem

Let  $\mathcal{P} = (P, \Gamma, \Delta)$  be a pushdown system and  $\mathcal{A} = (Q, \Gamma, \delta, P, F)$  be a  $\mathcal{P}$ -automaton. There exists an automaton  $\mathcal{A}_{post^*}$  recognizing post\*(Conf( $\mathcal{A}$ )). Moreover,  $\mathcal{A}_{post^*}$  can be constructed in  $\mathcal{O}(|P| \cdot |\Delta| \cdot (|Q| + |\Delta|) + |P| \cdot |\delta|)$ time and space.

# Verification of pushdown systems: the second step

### LTL model checking

IA159 Formal Verification Methods: LTL Model Checking of Pushdown Systems

# The global state-based LTL model checking problem for pushdown processes

Compute the set of all configurations of a given pushdown system  $\mathcal{P}$  that violate a given LTL formula  $\varphi$  (where a configuration *c* violates  $\varphi$  if there is a path starting from *c* and not satisfying  $\varphi$ ).

- state-based validity of atomic propositions
- labelling function L: (P × Γ) → 2<sup>AP</sup> assigns valid atomic propositions to every pair (p, γ) of a control location p and a topmost stack symbol γ
- pushdown system  $\mathcal{P}$  and L define Kripke structure
  - states = configurations of  $\mathcal{P}$
  - transition relation = immediate successor relation
  - no initial states (global model checking)
  - labelling function is an extension of L:  $L(\langle p, \gamma w \rangle) = L(p, \gamma)$

IA159 Formal Verification Methods: LTL Model Checking of Pushdown Systems

#### Büchi pushdown system = pushdown system with a set of accepting control locations.

An accepting run of a Büchi pushdown system is a path passing through some accepting control location infinitely often.

IA159 Formal Verification Methods: LTL Model Checking of Pushdown Systems

## Product

#### Product of

- a pushdown system  $\mathcal{P} = (P, \Gamma, \Delta)$  with a labelling *L* and
- a Büchi automaton  $\mathcal{A}_{\neg \varphi} = (2^{\mathcal{AP}(\varphi)}, Q, \delta, q_0, F)$

is a Büchi pushdown system  $\mathcal{BP} = ((P \times Q), \Gamma, \Delta', G)$ , where

 $\langle (p,q),\gamma \rangle \hookrightarrow \langle (p',q'),w \rangle \in \Delta' \text{ if } \langle p,\gamma \rangle \hookrightarrow \langle p',w \rangle \in \Delta \text{ and}$  $q' \in \delta(q, L(p,\gamma) \cap AP(\varphi))$ 

and  $G = P \times F$ .

Clearly, a configuration  $\langle p, w \rangle$  of  $\mathcal{P}$  violates  $\varphi$  if  $\mathcal{BP}$  has an accepting run starting from  $\langle (p, q_0), w \rangle$ .

#### The original model checking problem reduces to the following:

#### The accepting run problem

Compute the set  $C_a$  of configurations c of  $\mathcal{BP}$  such that  $\mathcal{BP}$  has an accepting run starting from c.

⇒ denotes the (reflexive and transitive) reachability relation.  $\stackrel{+}{\Rightarrow}$  denotes the (transitive) reachability relation.

We define the relation  $\stackrel{r}{\Rightarrow}$  on configurations of  $\mathcal{BP}$  as

$$c \stackrel{r}{\Rightarrow} c'$$
 if  $c \Rightarrow \langle g, u \rangle \stackrel{+}{\Rightarrow} c'$   
for some configuration  $\langle g, u \rangle$  with  $g \in G$ .

The head of a rule  $\langle p, \gamma \rangle \hookrightarrow \langle p', w \rangle$  is the configuration  $\langle p, \gamma \rangle$ . A head  $\langle p, \gamma \rangle$  is repeating if  $\langle p, \gamma \rangle \stackrel{r}{\Rightarrow} \langle p, \gamma v \rangle$  for some  $v \in \Gamma^*$ . The set of repeating heads of  $\mathcal{BP}$  is denoted by *R*.

#### Lemma

Let c be a configuration of a Büchi pushdown system  $\mathcal{BP}$ .  $\mathcal{BP}$  has an accepting run starting from  $c \iff$  there exists a repeating head  $\langle p, \gamma \rangle$  such that  $c \Rightarrow \langle p, \gamma w \rangle$  for some  $w \in \Gamma^*$ .

The implication " $\Leftarrow$ " is obvious. We prove " $\Rightarrow$ ".

IA159 Formal Verification Methods: LTL Model Checking of Pushdown Systems

**assume that**  $\mathcal{BP}$  has an accepting run

$$\langle p_0, w_0 \rangle, \langle p_1, w_1 \rangle, \langle p_2, w_2 \rangle, \dots$$

starting from from c

let  $i_0, i_1, \ldots$  be an increasing sequence of indices such that

$$|w_{i_0}| = \min\{|w_j| \mid j \ge 0\}$$

$$|w_{i_k}| = \min\{|w_j| \mid j > i_{k-1}\} \text{ for } k > 0$$

• once a configuration  $\langle p_{i_k}, w_{i_k} \rangle$  is reached, the rest of the run never looks at or changes the bottom  $|w_{i_k}| - 1$  stack symbols

## Proof

- let  $\gamma_{i_k}$  be the topmost symbol of  $w_{i_k}$  for each  $k \ge 0$
- as the number of pairs  $(p_{i_k}, \gamma_{i_k})$  is bounded by  $|P \times \Gamma|$ , there has to be a pair  $(p, \gamma)$  repeated infinitely many times
- moreover, since some  $g \in G$  becomes a control location infinitely often, we can select two indeces  $j_1 < j_2$  out of  $i_0, i_1, \ldots$  such that

$$\langle \boldsymbol{p}_{j_1}, \boldsymbol{w}_{j_1} \rangle = \langle \boldsymbol{p}, \gamma \boldsymbol{w} \rangle \stackrel{r}{\Rightarrow} \langle \boldsymbol{p}_{j_2}, \boldsymbol{w}_{j_2} \rangle = \langle \boldsymbol{p}, \gamma \boldsymbol{v} \boldsymbol{w} \rangle$$

for some  $w, v \in \Gamma^*$ 

- as *w* is never looked at or changed in the rest of the run, we have that  $\langle \boldsymbol{p}, \gamma \rangle \stackrel{r}{\Rightarrow} \langle \boldsymbol{p}, \gamma \boldsymbol{v} \rangle$
- this proves "⇒ "

#### Lemma

Let c be a configuration of a Büchi pushdown system  $\mathcal{BP}$ .  $\mathcal{BP}$  has an accepting run starting from  $c \iff$  there exists a repeating head  $\langle p, \gamma \rangle$  such that  $c \Rightarrow \langle p, \gamma w \rangle$  for some  $w \in \Gamma^*$ .

- the set of all configurations violating the considered formula φ can be computed as pre<sup>\*</sup>(RΓ<sup>\*</sup>), where RΓ<sup>\*</sup> = {⟨p, γw⟩ | ⟨p, γ⟩ ∈ R, w ∈ Γ<sup>\*</sup>}
- **as** R is finite,  $R\Gamma^*$  is clearly regular
- $pre^*(C)$  can be easily computed for regular sets C
- the only remaining step to solve the model checking problem is the algorithm computing R

Computing *R* is reduced to a graph-theoretic problem.

Given a  $\mathcal{BP} = (P, \Gamma, \Delta, G)$ , we construct a graph  $\mathcal{G} = (P \times \Gamma, E)$  representing the reachability relation between heads, i.e.

• nodes are the heads of  $\mathcal{BP}$ ,

E ⊆ (P × Γ) × {0,1} × (P × Γ) is the smallest relation satisfying the following rule:

#### Rule

If 
$$\langle p, \gamma \rangle \hookrightarrow \langle p'', v_1 \gamma' v_2 \rangle$$
 and  $\langle p'', v_1 \rangle \Rightarrow \langle p', \varepsilon \rangle$  then  
1  $((p, \gamma), 1, (p', \gamma')) \in E$  if  $\langle p'', v_1 \rangle \stackrel{r}{\Rightarrow} \langle p', \varepsilon \rangle$  or  $p \in G$   
2  $((p, \gamma), 0, (p', \gamma')) \in E$  otherwise.

#### Rule

If 
$$\langle p, \gamma \rangle \hookrightarrow \langle p'', v_1 \gamma' v_2 \rangle$$
 and  $\langle p'', v_1 \rangle \Rightarrow \langle p', \varepsilon \rangle$  then  
1  $((p, \gamma), 1, (p', \gamma')) \in E$  if  $\langle p'', v_1 \rangle \stackrel{r}{\Rightarrow} \langle p', \varepsilon \rangle$  or  $p \in G$   
2  $((p, \gamma), 0, (p', \gamma')) \in E$  otherwise.

Edges are labelled with 1 if an accepting control state is passed between the heads, by 0 otherwise.

Conditions  $\langle p'', v_1 \rangle \Rightarrow \langle p', \varepsilon \rangle$  or  $\langle p'', v_1 \rangle \stackrel{r}{\Rightarrow} \langle p', \varepsilon \rangle$  can be checked by the algorithm for  $pre^*(\{\langle p', \varepsilon \rangle\})$  or its small modification, respectively.

Once G is constructed, R can be computed using the fact that:

a head  $\langle p, \gamma \rangle$  is repeating  $\iff$   $(p, \gamma)$  is in a strongly connected a head  $\langle p, \gamma \rangle$  is repeating  $\iff$  component of  $\mathcal{G}$  which has an internal edge labelled with 1

### The graph $\mathcal{G}$ for $\mathcal{BP} = (\{p_0, p_1, p_2\}, \{\gamma_0, \gamma_1, \gamma_2\}, \Delta, \{p_2\})$ , where

$$\begin{split} \Delta &= \{ \quad \langle \pmb{p}_0, \gamma_0 \rangle \hookrightarrow \langle \pmb{p}_1, \gamma_1 \gamma_0 \rangle, \quad \langle \pmb{p}_2, \gamma_2 \rangle \hookrightarrow \langle \pmb{p}_0, \gamma_1 \rangle, \\ & \langle \pmb{p}_1, \gamma_1 \rangle \hookrightarrow \langle \pmb{p}_2, \gamma_2 \gamma_0 \rangle, \quad \langle \pmb{p}_0, \gamma_1 \rangle \hookrightarrow \langle \pmb{p}_0, \varepsilon \rangle \ \}. \end{split}$$

### Rule

If 
$$\langle \boldsymbol{p}, \boldsymbol{\gamma} \rangle \hookrightarrow \langle \boldsymbol{p}'', \boldsymbol{v}_1 \boldsymbol{\gamma}' \boldsymbol{v}_2 \rangle$$
 and  $\langle \boldsymbol{p}'', \boldsymbol{v}_1 \rangle \Rightarrow \langle \boldsymbol{p}', \varepsilon \rangle$  then  
1  $((\boldsymbol{p}, \boldsymbol{\gamma}), 1, (\boldsymbol{p}', \boldsymbol{\gamma}')) \in E$  if  $\langle \boldsymbol{p}'', \boldsymbol{v}_1 \rangle \stackrel{r}{\Rightarrow} \langle \boldsymbol{p}', \varepsilon \rangle$  or  $\boldsymbol{p} \in G$   
2  $((\boldsymbol{p}, \boldsymbol{\gamma}), 0, (\boldsymbol{p}', \boldsymbol{\gamma}')) \in E$  otherwise.

IA159 Formal Verification Methods: LTL Model Checking of Pushdown Systems

### The graph $\mathcal{G}$ for $\mathcal{BP} = (\{p_0, p_1, p_2\}, \{\gamma_0, \gamma_1, \gamma_2\}, \Delta, \{p_2\})$ , where

$$\begin{split} \Delta &= \{ \quad \langle \pmb{p}_0, \gamma_0 \rangle \hookrightarrow \langle \pmb{p}_1, \gamma_1 \gamma_0 \rangle, \quad \langle \pmb{p}_2, \gamma_2 \rangle \hookrightarrow \langle \pmb{p}_0, \gamma_1 \rangle, \\ & \langle \pmb{p}_1, \gamma_1 \rangle \hookrightarrow \langle \pmb{p}_2, \gamma_2 \gamma_0 \rangle, \quad \langle \pmb{p}_0, \gamma_1 \rangle \hookrightarrow \langle \pmb{p}_0, \varepsilon \rangle \ \}. \end{split}$$

### The graph $\mathcal{G}$ for $\mathcal{BP} = (\{p_0, p_1, p_2\}, \{\gamma_0, \gamma_1, \gamma_2\}, \Delta, \{p_2\})$ , where

$$\begin{split} \Delta &= \{ \quad \langle \pmb{p}_0, \gamma_0 \rangle \hookrightarrow \langle \pmb{p}_1, \gamma_1 \gamma_0 \rangle, \quad \langle \pmb{p}_2, \gamma_2 \rangle \hookrightarrow \langle \pmb{p}_0, \gamma_1 \rangle, \\ \langle \pmb{p}_1, \gamma_1 \rangle \hookrightarrow \langle \pmb{p}_2, \gamma_2 \gamma_0 \rangle, \quad \langle \pmb{p}_0, \gamma_1 \rangle \hookrightarrow \langle \pmb{p}_0, \varepsilon \rangle \ \}. \end{split}$$

#### Repeating heads: $\langle p_0, \gamma_0 \rangle, \langle p_1, \gamma_1 \rangle$

# Algorithm: notes

We give an algorithm computing R for a given  $\mathcal{BP}$  in normal form.

The algorithm runs in two phases.

1 It computes  $\mathcal{A}_{pre^*}$  recognizing  $pre^*(\{\langle p, \varepsilon \rangle \mid p \in P\})$ . Every transition  $(p, \gamma, p')$  of  $\mathcal{A}_{pre^*}$  signifies that  $\langle p, \gamma \rangle \Rightarrow \langle p', \varepsilon \rangle$ .

We enrich the transitions of  $\mathcal{A}_{pre^*}$ : transitions  $(p, \gamma, p')$  are replaced by  $(p, [\gamma, b], p')$  where *b* is a boolean. The meaning of  $(p, [\gamma, 1], p')$  should be that  $\langle p, \gamma \rangle \stackrel{r}{\Rightarrow} \langle p', \varepsilon \rangle$ .

It constructs the graph G, identifies its strongly conected components (e.g. using Tarjan's algorithm), and determines the set of repeating heads.

### We define G(p) = 1 if $p \in G$ and G(p) = 0 otherwise.

# Algorithm

Input:  $\mathcal{BP} = (P, \Gamma, \Delta, G)$  in normal form

Output: the set of repeating heads in  $\mathcal{BP}$ 

1 rel :=  $\emptyset$ : trans :=  $\emptyset$ :  $\Delta'$  :=  $\emptyset$ : forall  $\langle p, \gamma \rangle \hookrightarrow \langle p', \varepsilon \rangle \in \Delta$  do trans := trans  $\cup \{(p, [\gamma, G(p)], p')\};$ 2 3 while trans  $\neq \emptyset$  do pop  $t = (p, [\gamma, b], p')$  from trans; 4 5 if *t* ∉ *rel* then 6 7  $rel := rel \cup \{t\}$ : forall  $\langle p_1, \gamma_1 \rangle \hookrightarrow \langle p, \gamma \rangle \in \Delta$  do trans := trans  $\cup \{(p_1, [\gamma_1, b \lor G(p_1)], p')\};$ forall  $\langle p_1, \gamma_1 \rangle \xrightarrow{b'} \langle p, \gamma \rangle \in \Delta'$  do trans := trans  $\cup \{(p_1, [\gamma_1, b \lor b'], p')\};$ 8 9 forall  $\langle p_1, \gamma_1 \rangle \hookrightarrow \langle p, \gamma \gamma_2 \rangle \in \Delta$  do  $\Delta' := \Delta' \cup \{ \langle p_1, \gamma_1 \rangle \stackrel{b \lor G(p_1)}{\hookrightarrow} \langle p', \gamma_2 \rangle \};$ 10 11 forall  $(p', [\gamma_2, b'], p'') \in rel$  do 12  $\textit{trans} := \textit{trans} \cup \{(p_1, [\gamma_1, b \lor b' \lor G(p_1)], p'')\}; \text{ \ \% end of part 1}$ 13  $R := \emptyset: E := \emptyset:$ % beginning of part 2 forall  $\langle p, \gamma \rangle \hookrightarrow \langle p', \gamma' \rangle \in \Delta$  do  $E := E \cup \{((p, \gamma), G(p), (p', \gamma'))\};$ 14 forall  $\langle p, \gamma \rangle \stackrel{b}{\longleftrightarrow} \langle p', \gamma' \rangle \in \Delta'$  do  $E := E \cup \{((p, \gamma), b, (p', \gamma'))\};$ 15 16 forall  $\langle p, \gamma \rangle \hookrightarrow \langle p', \gamma' \gamma'' \rangle \in \Delta$  do  $E := E \cup \{((p, \gamma), G(p), (p', \gamma'))\};$ find all strongly connected components in  $\mathcal{G} = ((P \times \Gamma), E)$ ; 17 18 forall components C do 19 if C has a 1-edge then  $R := R \cup C$ ; return R 20

#### Theorem

Let  $\mathcal{BP} = (P, \Gamma, \Delta, G)$  be a Büchi pushdown system. The set of repeating heads R can be computed in  $\mathcal{O}(|P|^2 \cdot |\Delta|)$  time and  $\mathcal{O}(|P| \cdot |\Delta|)$  space.

The first part is similar to the algorithm computing  $A_{pre^*}$ . The size of  $\mathcal{G}$  is in  $\mathcal{O}(|P| \cdot |\Delta|)$ . Determining the strongly connected components takes linear time in the size of the graph *[Tarjan1972]*. The same holds for searching each component for an internal 1-edge.

#### Theorem

Let  $\mathcal{P}$  be a pushdown system and  $\varphi$  be an LTL formula. The global model checking problem can be solved in  $\mathcal{O}(|\mathcal{P}|^3 \cdot |\mathcal{B}|^3)$  time and  $\mathcal{O}(|\mathcal{P}|^2 \cdot |\mathcal{B}|^2)$  space, where  $\mathcal{B}$  is a Büchi automaton corresponding to  $\neg \varphi$ .

### $\text{LTL} \rightarrow \text{BA}$ via alternatring 1-weak automata

#### What is an alternating automaton?

How to translate it to a nondeterministic one?
