The Noisy Channel

- Prototypical case

- Model: probability of error (noise):
- Example: $p(0|1) = .3$ $p(1|1) = .7$ $p(1|0) = .4$ $p(0|0) = .6$
- The task:
known: the noisy output; want to know; the input (*decoding*)

Noisy Channel Applications

- OCR
– straightforward: text → print (adds noise), scan → image
- Handwriting recognition
– text → neurons, muscles ("noise"), scan/digitize → image
- Speech recognition (dictation, commands, etc.)
– text → conversion to acoustic signal ("noise") → acoustic waves
- Machine Translation
– text in target language → translation ("noise") → source language
- Also: Part of Speech Tagging
– sequence of tags → selection of word forms → text

The Golden Rule of OCR, ASR, HR, MT,...

- Recall:
$$p(A|B) = \frac{p(B|A)p(A)}{p(B)}$$
 (Bayes formula)
$$A_{best} = \operatorname{argmax}_A p(B|A)p(A)$$
 (The Golden Rule)
- $p(B|A)$: the acoustic/image/translation/lexical model
– application-specific name
– will explore later
- $p(A)$: *language model*

The Perfect Language Model

- Sequence of word forms (forget about tagging for the moment)
- Notation: $A \sim W = (w_1, w_2, w_3, \dots, w_d)$
- The big (modeling) question:
$$p(W) = ?$$
- Well, we know (Bayes/chain rule) →):
$$p(W) = p(w_1, w_2, w_3, \dots, w_d) = p(w_1) \times p(w_2|w_1) \times p(w_3|w_1, w_2) \times \dots \times p(w_d|w_1, w_2, \dots, w_{d-1})$$
- Not practical (even short $W \rightarrow$ too many parameters)

Markov Chain

- Unlimited memory (cf. previous foil):
– for w_i we know all its predecessors $w_1, w_2, w_3, \dots, w_{i-1}$
- Limited memory:
– we disregard "too old" predecessors
– remember only k previous words: $w_{i-k}, w_{i-k+1}, \dots, w_{i-1}$
– called " k^{th} order Markov approximation"
- + stationary character (no change over time):
$$p(W) \cong \prod_{i=1..d} p(w_i|w_{i-k}, w_{i-k+1}, \dots, w_{i-1}), d = |W|$$

n-gram Language Models

- $(n - 1)^{th}$ order Markov approximation \rightarrow n-gram LM:

$$p(W) =_{df} \prod_{i=1..d} p(w_i | \overset{\text{prediction}}{w_i} | \overset{\text{history}}{w_{i-n+1}, w_{i-n+2}, \dots, w_{i-1}})$$

- In particular (assume vocabulary $|V| = 60k$):

0-gram LM: uniform model,	$p(w) = 1/ V ,$	1 parameter
1-gram LM: unigram model,	$p(w),$	6×10^4 parameters
2-gram LM: bigram model,	$p(w_i w_{i-1}),$	3.6×10^9 parameters
3-gram LM: trigram model,	$p(w_i w_{i-2}, w_{i-1}),$	2.16×10^{14} parameters

LM: Observations

- How large n ?
 - nothing in enough (theoretically)
 - but anyway: as much as possible (\rightarrow close to "perfect" model)
 - empirically: 3
 - parameter estimation? (reliability, data availability, storage space, ...)
 - 4 is too much: $|V|=60k \rightarrow 1.296 \times 10^{19}$ parameters
 - but: 6–7 would be (almost) ideal (having enough data): in fact, one can recover original from 7-grams!
- Reliability $\sim (1/\text{Detail})$ (\rightarrow need compromise)
- For now, keep word forms (no "linguistic" processing)

The Length Issue

- $\forall n; \sum_{w \in \Omega^n} p(w) = 1 \Rightarrow \sum_{n=1.. \infty} \sum_{w \in \Omega^n} p(w) \gg 1 (\rightarrow \infty)$
- We want to model **all** sequences of words
 - for "fixed" length tasks: no problem – n fixed, sum is 1
 - tagging, OCR/handwriting (if words identified ahead of time)
 - for "variable" length tasks: have to account for
 - discount shorter sentences
- General model: for each sequence of words of length n , define $p'(w) = \lambda_n p(w)$ such that $\sum_{n=1.. \infty} \lambda_n = 1 \Rightarrow$

$$\sum_{n=1.. \infty} \sum_{w \in \Omega^n} p'(w) = 1$$
 e.g. estimate λ_n from data; or use normal or other distribution

Parameter Estimation

- Parameter: numerical value needed to compute $p(w|h)$
- From data (how else?)
- Data preparation:
 - get rid of formatting etc. ("text cleaning")
 - define words (separate but include punctuation, call it "word")
 - define sentence boundaries (insert "words" $\langle s \rangle$ and $\langle /s \rangle$)
 - letter case: keep, discard, or be smart:
 - name recognition
 - number type identification (these are huge problems per se!)
 - numbers: keep, replace by $\langle \text{num} \rangle$, or be smart (form \sim punctuation)

Maximum Likelihood Estimate

- MLE: Relative Frequency...
 - ...best predicts the data at hand (the "training data")
- Trigrams from training Data T:
 - count sequences of three words in T: $c_3(w_{i-2}, w_{i-1}, w_i)$
 - (NB: notation: just saying that three words follow each other)
 - count sequences of two words in T: $c_2(w_{i-1}, w_i)$
 - either use $c_2(y, z) = \sum_w c_3(y, z, w)$
 - or count differently at the beginning (& end) of the data!

$$p(w_i | w_{i-2}, w_{i-1}) =_{est.} \frac{c_3(w_{i-2}, w_{i-1}, w_i)}{c_2(w_{i-2}, w_{i-1})} \quad !$$

Character Language Model

- Use individual characters instead of words:

$$p(W) =_{df} \prod_{i=1..d} p(c_i | c_{i-n+1}, c_{i-n+2}, \dots, c_i)$$
- Same formulas etc.
- Might consider 4-grams, 5-grams or even more
- Good only for language comparison
- Transform cross-entropy between letter- and word-based models:

$$H_S(p_c) = H_S(p_w) / \text{avg. \# of characters/word in S}$$

LM: an Example

■ Training data:

<s> <s> He can buy the can of soda.

– Unigram:

$$p_1(\text{He}) = p_1(\text{buy}) = p_1(\text{the}) = p_1(\text{of}) = p_1(\text{soda}) = p_1(\cdot) = .125$$

$$p_1(\text{can}) = .25$$

– Bigram:

$$p_2(\text{He}|\text{<s>}) = 1, p_2(\text{can}|\text{He}) = 1, p_2(\text{buy}|\text{can}) = .5, p_2(\text{of}|\text{can}) = .5,$$

$$p_2(\text{the}|\text{buy}) = 1, \dots$$

– Trigram:

$$p_3(\text{He}|\text{<s>, <s>}) = 1, p_3(\text{can}|\text{<s>, He}) = 1, p_3(\text{buy}|\text{He, can}) = 1,$$

$$p_3(\text{of}|\text{the, can}) = 1, \dots, p_3(\cdot|\text{of, soda}) = 1.$$

– Entropy:

$$H(p_1) = 2.75, H(p_2) = .25, H(p_3) = 0 \leftarrow \text{Great?!}$$

LM: an Example (The Problem)

■ Cross-entropy:

■ $S = \text{<s><s>}$ It was the greatest buy of all.

■ Even $H_S(p_1)$ fails ($= H_S(p_2) = H_S(p_3) = \infty$), because:

■ all unigrams but $p_1(\text{the})$, $p_1(\text{buy})$, $p_1(\text{of})$ and $p_1(\cdot)$ are 0.

■ all bigram probabilities are 0.

■ all trigram probabilities are 0.

■ We want: to make all (theoretically possible*) probabilities non-zero.

*in fact, all: remember our graph from day 1?
