

Chapter 4: SQL

- Basic Structure
- Set Operations
- Aggregate Functions
- Null Values
- Nested Subqueries
- Derived Relations
- Views
- Modification of the Database
- Joined Relations
- Data Definition Language
- Embedded SQL

Basic Structure

- SQL is based on set and relational operations with certain modifications and enhancements
- A typical SQL query has the form:

select A_1, A_2, \dots, A_n
from r_1, r_2, \dots, r_m
where P

- A_i s represent attributes
 - r_i s represent relations
 - P is a predicate.
- This query is equivalent to the relational algebra expression:
- $$\Pi_{A_1, A_2, \dots, A_n}(\sigma_P(r_1 \times r_2 \times \dots \times r_m))$$
- The result of an SQL query is a relation.

The select Clause

- The **select** clause corresponds to the projection operation of the relational algebra. It is used to list the attributes desired in the result of a query.

- Find the names of all branches in the *loan* relation

```
select branch-name  
from loan
```

In the “pure” relational algebra syntax, this query would be:

$$\Pi_{branch-name}(loan)$$

- An asterisk in the select clause denotes “all attributes”

```
select *  
from loan
```

The select Clause (Cont.)

- SQL allows duplicates in relations as well as in query results.
- To force the elimination of duplicates, insert the keyword **distinct** after **select**.

Find the names of all branches in the *loan* relation, and remove duplicates

```
select distinct branch-name  
from loan
```

- The keyword **all** specifies that duplicates not be removed.

```
select all branch-name  
from loan
```

The select Clause (Cont.)

- The **select** clause can contain arithmetic expressions involving the operators, +, −, *, and /, and operating on constants or attributes of tuples.
- The query:

```
select branch-name, loan-number, amount * 100  
from loan
```

would return a relation which is the same as the *loan* relation, except that the attribute *amount* is multiplied by 100

The where Clause

- The **where** clause corresponds to the selection predicate of the relational algebra. It consists of a predicate involving attributes of the relations that appear in the **from** clause.
- Find all loan numbers for loans made at the Perryridge branch with loan amounts greater than \$1200.

select *loan-number*

from *loan*

where *branch-name* = "Perryridge" **and** *amount* > 1200

- SQL uses the logical connectives **and**, **or**, and **not**. It allows the use of arithmetic expressions as operands to the comparison operators.

The where Clause (Cont.)

- SQL includes a **between** comparison operator in order to simplify **where** clauses that specify that a value be less than or equal to some value and greater than or equal to some other value.
- Find the loan number of those loans with loan amounts between \$90,000 and \$100,000 (that is, \geq \$90,000 and \leq \$100,000)

```
select loan-number  
from loan  
where amount between 90000 and 100000
```

The from Clause

- The **from** clause corresponds to the Cartesian product operation of the relational algebra. It lists the relations to be scanned in the evaluation of the expression.
- Find the Cartesian product *borrower* \times *loan*

```
select *  
from borrower, loan
```

- Find the name and loan number of all customers having a loan at the Perryridge branch.

```
select distinct customer-name, borrower.loan-number  
from borrower, loan  
where borrower.loan-number = loan.loan-number and  
branch-name = "Perryridge"
```

The Rename Operation

- The SQL mechanism for renaming relations and attributes is accomplished through the **as** clause:

old-name as new-name

- Find the name and loan number of all customers having a loan at the Perryridge branch; replace the column name *loan-number* with the name *loan-id*.

```
select distinct customer-name, borrower.loan-number as loan-id  
from borrower, loan  
where borrower.loan-number = loan.loan-number and  
branch-name = "Perryridge"
```

Tuple Variables

- Tuple variables are defined in the **from** clause via the use of the **as** clause.
- Find the customer names and their loan numbers for all customers having a loan at some branch.

```
select distinct customer-name, T.loan-number  
from borrower as T, loan as S  
where T.loan-number = S.loan-number
```

- Find the names of all branches that have greater assets than some branch located in Brooklyn.

```
select distinct T.branch-name  
from branch as T, branch as S  
where T.assets > S.assets and S.branch-city = "Brooklyn"
```

String Operations

- SQL includes a string-matching operator for comparisons on character strings. Patterns are described using two special characters:
 - percent (%). The % character matches any substring.
 - underscore (_). The _ character matches any character.
- Find the names of all customers whose street includes the substring 'Main'.

```
select customer-name  
from customer  
where customer-street like "%Main%"
```

- Match the name "Main%"

```
like "Main\%" escape "\"
```

Ordering the Display of Tuples

- List in alphabetic order the names of all customers having a loan at Perryridge branch

```
select distinct customer-name  
from borrower, loan  
where borrower.loan-number = loan.loan-number and  
       branch-name = "Perryridge"  
order by customer-name
```

- We may specify **desc** for descending order or **asc** for ascending order, for each attribute; ascending order is the default.
- SQL must perform a sort to fulfill an **order by** request. Since sorting a large number of tuples may be costly, it is desirable to sort only when necessary.

Duplicates

- In relations with duplicates, SQL can define how many copies of tuples appear in the result.
- *Multiset* versions of some of the relational algebra operators – given multiset relations r_1 and r_2 :
 1. If there are c_1 copies of tuple t_1 in r_1 , and t_1 satisfies selection σ_θ , then there are c_1 copies of t_1 in $\sigma_\theta(r_1)$.
 2. For each copy of tuple t_1 in r_1 , there is a copy of tuple $\Pi_A(t_1)$ in $\Pi_A(r_1)$, where $\Pi_A(t_1)$ denotes the projection of the single tuple t_1 .
 3. If there are c_1 copies of tuple t_1 in r_1 and c_2 copies of tuple t_2 in r_2 , there are $c_1 \times c_2$ copies of the tuple $t_1.t_2$ in $r_1 \times r_2$.

Duplicates (Cont.)

- Suppose relations r_1 with schema (A, B) and r_2 with schema (C) are the following multisets:

$$r_1 = \{(1, a), (2, a)\} \quad r_2 = \{(2), (3), (3)\}$$

- Then $\Pi_B(r_1)$ would be $\{(a), (a)\}$, while $\Pi_B(r_1) \times r_2$ would be

$$\{(a, 2), (a, 2), (a, 3), (a, 3), (a, 3), (a, 3)\}$$

- SQL duplicate semantics:

select A_1, A_2, \dots, A_n
from r_1, r_2, \dots, r_m
where P

is equivalent to the *multiset* version of the expression:

$$\Pi_{A_1, A_2, \dots, A_n}(\sigma_P(r_1 \times r_2 \times \dots \times r_m))$$

Set Operations

- The set operations **union**, **intersect**, and **except** operate on relations and correspond to the relational algebra operations \cup , \cap , and $-$.
- Each of the above operations automatically eliminates duplicates; to retain all duplicates use the corresponding multiset versions **union all**, **intersect all** and **except all**. Suppose a tuple occurs m times in r and n times in s , then, it occurs:
 - $m + n$ times in r **union all** s
 - $\min(m, n)$ times in r **intersect all** s
 - $\max(0, m - n)$ times in r **except all** s

Set Operations

- Find all customers who have a loan, an account, or both:
(**select** *customer-name* **from** *depositor*)
union
(**select** *customer-name* **from** *borrower*)
- Find all customers who have both a loan and an account.
(**select** *customer-name* **from** *depositor*)
intersect
(**select** *customer-name* **from** *borrower*)
- Find all customers who have an account but no loan.
(**select** *customer-name* **from** *depositor*)
except
(**select** *customer-name* **from** *borrower*)

Aggregate Functions

These functions operate on the multiset of values of a column of a relation, and return a value

avg: average value

min: minimum value

max: maximum value

sum: sum of values

count: number of values

Aggregate Functions (Cont.)

- Find the average account balance at the Perryridge branch.

```
select avg (balance)  
from account  
where branch-name = "Perryridge"
```

- Find the number of tuples in the *customer* relation.

```
select count (*)  
from customer
```

- Find the number of depositors in the bank

```
select count (distinct customer-name)  
from depositor
```

Aggregate Functions – Group By

- Find the number of depositors for each branch.

```
select branch-name, count (distinct customer-name)  
from depositor, account  
where depositor.account-number = account.account-number  
group by branch-name
```

Note: Attributes in **select** clause outside of aggregate functions must appear in **group by** list.

Aggregate Functions – Having Clause

- Find the names of all branches where the average account balance is more than \$1,200

```
select branch-name, avg (balance)  
from account  
group by branch-name  
having avg (balance) > 1200
```

Note: predicates in the **having** clause are applied after the formation of groups

Null Values

- It is possible for tuples to have a null value, denoted by *null*, for some of their attributes; *null* signifies an unknown value or that a value does not exist.
- The result of any arithmetic expression involving *null* is *null*.
- Roughly speaking, all comparisons involving *null* return *false*.
More precisely,
 - Any comparison with *null* returns *unknown*
 - (*true or unknown*) = *true*, (*false or unknown*) = *unknown*
(*unknown or unknown*) = *unknown*,
(*true and unknown*) = *unknown*, (*false and unknown*) = *false*,
(*unknown and unknown*) = *unknown*
 - Result of **where** clause predicate is treated as *false* if it evaluates to *unknown*
 - “*P is unknown*” evaluates to true if predicate *P* evaluates to *unknown*

Null Values (Cont.)

- Find all loan numbers which appear in the *loan* relation with null values for *amount*.

```
select loan-number  
from loan  
where amount is null
```

- Total all loan amounts

```
select sum (amount)  
from loan
```

Above statement ignores null amounts; result is null if there is no non-null amount.

- All aggregate operations except **count(*)** ignore tuples with null values on the aggregated attributes.

Nested Subqueries

- SQL provides a mechanism for the nesting of subqueries.
- A subquery is a **select-from-where** expression that is nested within another query.
- A common use of subqueries is to perform tests for set membership, set comparisons, and set cardinality.

Set Membership

- $F \text{ in } r \Leftrightarrow \exists t \in r (t = F)$

(5 in

0
4
5

) = true

(5 in

0
4
6

) = false

(5 not in

0
4
6

) = true

Example Query

- Find all customers who have both an account and a loan at bank.

```
select distinct customer-name  
from borrower  
where customer-name in (select customer-name  
                                from depositor)
```

- Find all customers who have a loan at the bank but do not have an account at the bank.

```
select distinct customer-name  
from borrower  
where customer-name not in (select customer-name  
                                from depositor)
```

Example Query

- Find all customers who have both an account and a loan at the Perryridge branch.

```
select distinct customer-name
from borrower, loan
where borrower.loan-number = loan.loan-number and
       branch-name = "Perryridge" and
       (branch-name, customer-name) in
       (select branch-name, customer-name
        from depositor, account
        where depositor.account-number =
              account.account-number)
```

Set Comparison

- Find all branches that have greater assets than some branch located in Brooklyn.

```
select distinct T.branch-name  
from branch as T, branch as S  
where T.assets > S.assets and  
          S.branch-city = "Brooklyn"
```

The Some Clause

- $F \langle \text{comp} \rangle \text{ some } r \Leftrightarrow \exists t(t \in r \wedge [F \langle \text{comp} \rangle t])$

Where $\langle \text{comp} \rangle$ can be: $<, \leq, >, \geq, =, \neq$

$(5 < \text{some } \begin{array}{|c|} \hline 0 \\ \hline 5 \\ \hline 6 \\ \hline \end{array}) = \text{true}$
(read: 5 < some tuple in the relation)

$(5 < \text{some } \begin{array}{|c|} \hline 0 \\ \hline 5 \\ \hline \end{array}) = \text{false}$

$(5 = \text{some } \begin{array}{|c|} \hline 0 \\ \hline 5 \\ \hline \end{array}) = \text{true}$

$(5 \neq \text{some } \begin{array}{|c|} \hline 0 \\ \hline 5 \\ \hline \end{array}) = \text{true (since } 0 \neq 5)$

- $(= \text{ some}) \equiv \text{in}$
- However, $(\neq \text{ some}) \not\equiv \text{not in}$

Example Query

- Find all branches that have greater assets than some branch located in Brooklyn.

```
select branch-name
from branch
where assets > some
      (select assets
from branch
where branch-city = "Brooklyn")
```

The All Clause

- $F \langle \text{comp} \rangle \text{ all } r \Leftrightarrow \forall t (t \in r \wedge [F \langle \text{comp} \rangle t])$

$$(5 \langle \text{all} \rangle \begin{array}{|c|} \hline 0 \\ \hline 5 \\ \hline 6 \\ \hline \end{array}) = \text{false}$$

$$(5 \langle \text{all} \rangle \begin{array}{|c|} \hline 6 \\ \hline 10 \\ \hline \end{array}) = \text{true}$$

$$(5 \langle \text{all} \rangle \begin{array}{|c|} \hline 4 \\ \hline 5 \\ \hline \end{array}) = \text{false}$$

$$(5 \langle \neq \text{all} \rangle \begin{array}{|c|} \hline 4 \\ \hline 6 \\ \hline \end{array}) = \text{true (since } 5 \neq 4 \text{ and } 5 \neq 6)$$

- $(\neq \text{all}) \equiv \text{not in}$
- However, $(= \text{all}) \not\equiv \text{in}$

Example Query

- Find the names of all branches that have greater assets than all branches located in Brooklyn.

```
select branch-name
from branch
where assets > all
      (select assets
from branch
where branch-city = "Brooklyn")
```

Test for Empty Relations

- The **exists** construct returns the value **true** if the argument subquery is nonempty.
- **exists** $r \Leftrightarrow r \neq \emptyset$
- **not exists** $r \Leftrightarrow r = \emptyset$

Example Query

- Find all customers who have an account at all branches located in Brooklyn.

```
select distinct S.customer-name
from depositor as S
where not exists (
    (select branch-name
     from branch
     where branch-city = "Brooklyn")
except
    (select R.branch-name
     from depositor as T, account as R
     where T.account-number = R.account-number and
           S.customer-name = T.customer-name))
```

- Note that $X - Y = \emptyset \Leftrightarrow X \subseteq Y$

Test for Absence of Duplicate Tuples

- The **unique** construct tests whether a subquery has any duplicate tuples in its result.
- Find all customers who have only one account at the Perryridge branch.

```
select T.customer-name  
from depositor as T  
where unique (  
    select R.customer-name  
from account, depositor as R  
where T.customer-name = R.customer-name and  
        R.account-number = account.account-number and  
        account.branch-name = "Perryridge")
```

Example Query

- Find all customers who have at least two accounts at the Perryridge branch.

```
select distinct T.customer-name  
from depositor T  
where not unique (  
    select R.customer-name  
    from account, depositor as R  
    where T.customer-name = R.customer-name and  
        R.account-number = account.account-number and  
        account.branch-name = "Perryridge")
```

Derived Relations

- Find the average account balance of those branches where the average account balance is greater than \$1200.

```
select branch-name, avg-balance
from (select branch-name, avg (balance)
       from account
       group by branch-name)
as result (branch-name, avg-balance)
where avg-balance > 1200
```

Note that we do not need to use the **having** clause, since we compute in the **from** clause the temporary relation *result*, and the attributes of *result* can be used directly in the **where** clause.

Views

- Provide a mechanism to hide certain data from the view of certain users. To create a view we use the command:

create view v as <query expression>

where:

- <query expression> is any legal expression
- the view name is represented by v

Example Queries

- A view consisting of branches and their customers

create view *all-customer* **as**

(select *branch-name, customer-name*

from *depositor, account*

where *depositor.account-number = account.account-number*)

union

(select *branch-name, customer-name*

from *borrower, loan*

where *borrower.loan-number = loan.loan-number*)

- Find all customers of the Perryridge branch

select *customer-name*

from *all-customer*

where *branch-name = "Perryridge"*

Modification of the Database – Deletion

- Delete all account records at the Perryridge branch

```
delete from account  
where branch-name = "Perryridge"
```

- Delete all accounts at every branch located in Needham.

```
delete from account  
where branch-name in (select branch-name  
                        from branch  
                        where branch-city = "Needham")
```

```
delete from depositor  
where account-number in (select account-number  
                                from branch, account  
                                where branch-city = "Needham"  
                                and branch.branch-name = account.branch-name)
```

Example Query

- Delete the records of all accounts with balances below the average at the bank

```
delete from account  
where balance < (select avg (balance)  
                    from account)
```

- Problem: as we delete tuples from *deposit*, the average balance changes
- Solution used in SQL:
 1. First, compute **avg** balance and find all tuples to delete
 2. Next, delete all tuples found above (without recomputing **avg** or retesting the tuples)

Modification of the Database – Insertion

- Add a new tuple to *account*

```
insert into account  
values ("Perryridge", A-9732, 1200)
```

or equivalently

```
insert into account (branch-name, balance, account-number)  
values ("Perryridge", 1200, A-9732)
```

- Add a new tuple to *account* with *balance* set to null

```
insert into account  
values ("Perryridge", A-777, null)
```

Modification of the Database – Insertion

- Provide as a gift for all loan customers of the Perryridge branch, a \$200 savings account. Let the loan number serve as the account number for the new savings account

insert into *account*

select *branch-name, loan-number, 200*
from *loan*
where *branch-name = "Perryridge"*

insert into *depositor*

select *customer-name, loan-number*
from *loan, borrower*
where *branch-name = "Perryridge"*
and *loan.account-number = borrower.account-number*

Modification of the Database – Updates

- Increase all accounts with balances over \$10,000 by 6%, all other accounts receive 5%.

- Write two **update** statements:

```
update account  
set balance = balance * 1.06  
where balance > 10000
```

```
update account  
set balance = balance * 1.05  
where balance ≤ 10000
```

- The order is important
- Can be done better using the **case** statement (Exercise 4.11)

Update of a View

- Create a view of all loan data in the *loan* relation, hiding the *amount* attribute

```
create view branch-loan as  
select branch-name, loan-number  
from loan
```

- Add a new tuple to *branch-loan*

```
insert into branch-loan  
values ("Perryridge", "L-307")
```

This insertion must be represented by the insertion of the tuple

("Perryridge", "L-307", *null*)

into the *loan* relation.

- Updates on more complex views are difficult or impossible to translate, and hence are disallowed.

Joined Relations

- Join operations take two relations and return as a result another relation.
- These additional operations are typically used as subquery expressions in the **from** clause.
- Join condition – defines which tuples in the two relations match, and what attributes are present in the result of the join.
- Join type – defines how tuples in each relation that do not match any tuple in the other relation (based on the join condition) are treated.

Join Types

inner join
left outer join
right outer join
full outer join

Join Conditions

natural
on <predicate>
using (A_1, A_2, \dots, A_n)

Joined Relations – Datasets for Examples

- Relation *loan*

<i>branch-name</i>	<i>loan-number</i>	<i>amount</i>
Downtown	L-170	3000
Redwood	L-230	4000
Perryridge	L-260	1700

- Relation *borrower*

<i>customer-name</i>	<i>loan-number</i>
Jones	L-170
Smith	L-230
Hayes	L-155

Joined Relations – Examples

- **loan inner join borrower on**
loan.loan-number = borrower.loan-number

<i>branch-name</i>	<i>loan-number</i>	<i>amount</i>	<i>customer-name</i>	<i>loan-number</i>
Downtown	L-170	3000	Jones	L-170
Redwood	L-230	4000	Smith	L-230

- **loan left outer join borrower on**
loan.loan-number=borrower.loan-number

<i>branch-name</i>	<i>loan-number</i>	<i>amount</i>	<i>customer-name</i>	<i>loan-number</i>
Downtown	L-170	3000	Jones	L-170
Redwood	L-230	4000	Smith	L-230
Perryridge	L-260	1700	<i>null</i>	<i>null</i>

Joined Relations – Examples

- *loan natural inner join borrower*

<i>branch-name</i>	<i>loan-number</i>	<i>amount</i>	<i>customer-name</i>
Downtown	L-170	3000	Jones
Redwood	L-230	4000	Smith

- *loan natural right outer join borrower*

<i>branch-name</i>	<i>loan-number</i>	<i>amount</i>	<i>customer-name</i>
Downtown	L-170	3000	Jones
Redwood	L-230	4000	Smith
null	L-155	null	Hayes

Joined Relations – Examples

- *loan full outer join borrower using (loan-number)*

<i>branch-name</i>	<i>loan-number</i>	<i>amount</i>	<i>customer-name</i>
Downtown	L-170	3000	Jones
Redwood	L-230	4000	Smith
Perryridge	L-260	1700	<i>null</i>
<i>null</i>	L-155	<i>null</i>	Hayes

- Find all customers who have either an account or a loan (but not both) at the bank.

```
select customer-name  
from (depositor natural full outer join borrower)  
where account-number is null or loan-number is null
```

Data Definition Language (DDL)

Allows the specification of not only a set of relations but also information about each relation, including:

- The schema for each relation.
- The domain of values associated with each attribute.
- Integrity constraints.
- The set of indices to be maintained for each relation.
- Security and authorization information for each relation.
- The physical storage structure of each relation on disk.

Domain Types in SQL

- **char(*n*)**. Fixed length character string, with user-specified length *n*.
- **varchar(*n*)**. Variable length character strings, with user-specified maximum length *n*.
- **int**. Integer (a finite subset of the integers that is machine-dependent).
- **smallint**. Small integer (a machine-dependent subset of the integer domain type).
- **numeric(*p,d*)**. Fixed point number, with user-specified precision of *p* digits, with *n* digits to the right of decimal point.

Domain Types in SQL (Cont.)

- **real, double precision.** Floating point and double-precision floating point numbers, with machine-dependent precision.
 - **float(n).** Floating point number, with user-specified precision of at least n digits.
 - **date.** Dates, containing a (4 digit) year, month and date.
 - **time.** Time of day, in hours, minutes and seconds.
- Null values are allowed in all the domain types. Declaring an attribute to be **not null** prohibits null values for that attribute.
 - **create domain** construct in SQL-92 creates user-defined domain types

create domain *person-name* char(20) not null

Create Table Construct

- An SQL relation is defined using the **create table** command:

```
create table  $r$  ( $A_1 D_1, A_2 D_2, \dots, A_n D_n,$   
                 $\langle$ integrity-constraint $_1$  $\rangle,$   
                 $\dots,$   
                 $\langle$ integrity-constraint $_k$  $\rangle$ )
```

- r is the name of the relation
 - each A_i is an attribute name in the schema of relation r
 - D_i is the data type of values in the domain of attribute A_i
- Example:

```
create table branch  
    (branch-name      char(15) not null,  
     branch-city     char(30),  
     assets           integer)
```

Integrity Constraints In Create Table

- **not null**
- **primary key** (A_1, \dots, A_n)
- **check** (P), where P is a predicate 

Example: Declare *branch-name* as the primary key for *branch* and ensure that the values of *assets* are non-negative.

```
create table branch
  (branch-name    char(15) not null,
   branch-city   char(30),
   assets         integer,
   primary key (branch-name),
   check (assets >= 0))
```

- **primary key** declaration on an attribute automatically ensures **not null** in SQL-92

Drop and Alter Table Constructs

- The **drop table** command deletes all information about the dropped relation from the database.
- The **alter table** command is used to add attributes to an existing relation. All tuples in the relation are assigned *null* as the value for the new attribute. The form of the **alter table** command is

alter table r add A D

where A is the name of the attribute to be added to relation r and D is the domain of A .

- The **alter table** command can also be used to drop attributes of a relation

alter table r drop A

where A is the name of an attribute of relation r .

Embedded SQL

- The SQL standard defines embeddings of SQL in a variety of programming languages such as Pascal, PL/I, Fortran, C, and Cobol.
- A language in which SQL queries are embedded is referred to as a *host* language, and the SQL structures permitted in the host language comprise *embedded* SQL.
- The basic form of these languages follows that of the System R embedding of SQL into PL/I.
- EXEC SQL statement is used to identify embedded SQL requests to the preprocessor

EXEC SQL <embedded SQL statement > END EXEC

Example Query

From within a host language, find the names and account numbers of customers with more than the variable *amount* dollars in some account.

- Specify the query in SQL and declare a *cursor* for it

EXEC SQL

declare *c* **cursor for**

select *customer-name, account-number*

from *depositor, account*

where *depositor.account-number = account.account-number*

and *account.balance > :amount*

END-EXEC

Embedded SQL (Cont.)

- The **open** statement causes the query to be evaluated

EXEC SQL **open** *c* END-EXEC

- The **fetch** statement causes the values of one tuple in the query result to be placed in host language variables.

EXEC SQL **fetch** *c into* *:cn* *:an* END-EXEC

Repeated calls to **fetch** get successive tuples in the query result; a variable in the SQL communication area indicates when end-of-file is reached.

- The **close** statement causes the database system to delete the temporary relation that holds the result of the query.

EXEC SQL **close** *c* END-EXEC

Dynamic SQL

- Allows programs to construct and submit SQL queries at run time.
- Example of the use of dynamic SQL from within a C program.

```
char * sqlprog = "update account set balance = balance *1.05  
where account-number = ?"
```

```
EXEC SQL prepare dynprog from :sqlprog;
```

```
char account[10] = "A-101";
```

```
EXEC SQL execute dynprog using :account;
```

- The dynamic SQL program contains a ?, which is a place holder for a value that is provided when the SQL program is executed.

Other SQL Features

- *Fourth-generation languages* – special language to assist application programmers in creating templates on the screen for a user interface, and in formatting data for report generation; available in most commercial database products
- SQL sessions – provide the abstraction of a client and a server (possibly remote)
 - client *connects* to an SQL server, establishing a session
 - executes a series of statements
 - *disconnects* the session
 - can *commit* or *rollback* the work carried out in the session
- An SQL environment contains several components, including a user identifier, and a *schema*, which identifies which of several schemas a session is using.
