# Lesson 6 HDR: Tone Mapping, Bloom effect PV227 – GPU Rendering

Jiří Chmelík, Jan Čejka Fakulta informatiky Masarykovy univerzity

24. 10. 2016

# HDR – Theory Basics

### High Dynamic Range

- HDRI ("high dynamic range imaging")
- HDRR ("high dynamic range rendering")
- Developed to make on-screeen rendering more natural (human-eye like)
- Range of intensities:
  - software: often only 8 bits  $\Rightarrow$  only 256 steps
  - hardware: quite limited (black is not black, bright white is much less brighter than sun light)
  - human eye...

# Human Eye – Range of perceptible intensities

illumination condition	illuminance (lux)
Full moon	1
Street lighting	10
Home lighting	30 to 300
Office desk lighting	100 to 1 000
Surgery lighting	10 000
Direct sunlight	100 000

Vast range of perceptible intensities. But not concurrently!

# Human Eye Perception Imperfection

What are the colors of marked fields?

Lesson 6 - HDR

# Capturing, Rendering

• We can capture (or model) and "realistically" render both the dark scenes and the bright scenes without HDR.

#### • The problem is with scenes with high dynamic range...

# Capturing HDR Content

To capture HDR content with LDR camera:

- ① capture more shots with different exposure settings
- ② Compose final image with "tone mapping" technique

Source: https://en.wikipedia.org/wiki/High-dynamic-range\_imaging

# **Rendering HDR Content**

Various methods to convert HDR content into LDR image exists:

#### Contrast reduction

### Local tone mapping

- Bloom (blooming, glow) "overflowing" of light to surrounding objects
- Other buffers, techniques:
  - light maps,
  - skybox,
  - ► ...
- Advanced technique: "Temporally Coherent Local Tone Mapping": https://youtu.be/6yltM8UB7k4

# Implemantation of HDR Rendering

- Common color buffer format: R8G8B8
  - ► Don't forget: values are clamped to range < 0.0, 1.0 >
- We need high dynamic range buffer
  - We can simply switch to R16G16B16A16F
  - No clamping of values

glTexImage2D(GL\_TEXTURE\_2D, 0, GL\_RGBA16F, win\_width, win\_height, 0, GL\_RGBA, GL\_FLOAT, nullptr);

- Set-up HDR buffer (TASK 1)
- First pass: compute lighting of scene into HDR buffer
  - The SAME computations, just no clamping of values
- Second pass: use one of algorithms to tone map HDR buffer to (LDR) frame-buffer (TASK 2)
- Following passes: reuse existing HDR buffer to other effects...

```
Among the simplest tone mapping techniques – simple remapping of HDR values to range < 0.0, 1.0 > by division.
```

```
// read color from HDR texture
vec3 hdrColor = texture(hdrBuffer, TexCoords).rgb;
// simple reinhard mapping
vec3 result = hdrColor / (hdrColor + vec3(1.0));
```

## Tone Mapping – "Adjustable Exposure" technique

Allow us to render scene with different exposures:

 $rgb = 1 - 2^{-hdr * exposure}$ 

// read color from HDR texture
vec3 hdrColor = texture(hdrBuffer, TexCoords).rgb;

// Exposure tone mapping
vec3 mapped = vec3(1.0) - exp2(-hdrColor \* exposure);

Could be combined with all tone mapping techniques.

```
// read from texture
// Do a tone mapping
vec3 mapped = ...
```

```
// Gamma correction
mapped = pow(mapped, vec3(1.0 / gamma));
```

# Bloom Effect (Blooming, Glow)

- Imperfection of human eye (or camera sensor) which is overwhelmed by bright light. Light is "overflowing" to surrounding cells (pixels).
- In CG added artificially to increase realism.
- Bloom can be used also in LDR, but with HDR make more sense.

Figure Source: http://www.nationalgeographic.com/photography/photo-tips/overexposure-on-purpose-richardson/

## Bloom Effect – CG example

Source: http://learnopengl.com/#!Advanced-Lighting/Bloom

- 1 Lit the scene (as always)
- ② Fill buffer of pixels with high brightness (highlights) (TASK 3)
- 3 Blur the highlights buffer to simulate glow effect (TASK 4)
- ④ Compose original rendering with blurred highlights (TASK 5)

- How many passes we need?
- Do we need deffered shading? Can we exploit it? How?
- Where is HDR in this?

- In what shader?
- Compare fragment brightness to some threshold
  - ► We are working with HDR buffers, treshold could be simply 1.0f
  - ► Hint: brightness of pixel...vec3(0.299f, 0.587f, 0.114f)

Blurring shader

- What is difference from blur\_SSAO shader?
- Blur possibilities:
  - Simple average
  - Gaussian
  - Repeated blurring later
  - Separable kernels
  - ▶ ...
- Think about effectiveness

Could be complicated in LDR, pretty easy with HDR buffers:

- Simply add values of lit scene and blurred highlights
- ② Use tone mapping as before

# What Next?

- How to combine effects?
  - ► We can have: SSAO, HDR (Tone mapping + Bloom), DoF, Grain, Flares, etc.
  - Lots of buffers needed lots of memory needed
  - Lots of "logic" needed to do it effectively
- Post-effect double buffering trick:
  - For combining various post-process effects
  - "Double buffer" for blurring bonus task (TASK4b)
    - ★ Is it faster than separable kernels blurring?

### **Assignment 1**

• John Hable: Uncharted 2: HDR lighting

- Extensive desciption of HDR in context of AAA game:
  - ★ gamma,
  - ★ linear space,
  - ★ filmic tone mapping,
  - ★ A lot more
