## Outline

- ① Sampling in 1D
  - Comb function
  - Nyquist-Shannon theorem
  - Aliasing
  - Reconstruction/Interpolation
- ② Sampling in 2D
  - Comb function
  - Aliasing
  - Reconstruction/Interpolation
- ③ Resampling in 1D
  - Design of an ideal resampling filter
- ④ Resampling in 2D
  - Elliptical Weighted Average (EWA)

## Comb function

In 1D space

$$\text{III}(x) = \sum_{n=-\infty}^{\infty} \delta(x - n)$$

**Notice:** “III” is pronounced as *shah* (Cyrilic character).

## Comb function

Some properties

- $\text{III}(-x) = \text{III}(x)$
- $\text{III}(x + n) = \text{III}(x)$
- $\text{III}(x - \frac{1}{2}) = \text{III}(x + \frac{1}{2})$
- $\text{III}(x) = 0 \quad x \neq n$
- $\text{III}(ax) = \frac{1}{|a|} \sum \delta(x - \frac{n}{a})$
- $\text{III}(\frac{x}{\tau}) \supset \tau \text{III}(\tau\omega)$

# Sampling

## Sampling in 1D:

- a process of converting a continuous signal into a discrete sequence.
- a multiplication with comb function:

$$\text{III}(x)f(x) = \sum_{n=-\infty}^{\infty} f(n)\delta(x - n)$$

**Question:** What happens in frequency (Fourier) domain?

# Sampling

Image domain *versus* Fourier domain

## Image/Time domain:

- multiplication of the function  $f$  and  $\text{III}$
- sampling

## Fourier domain:

- convolution of the function  $FT(f)$  and  $FT(\text{III})$
- convolution with Dirac impulses  $\rightarrow$  replication of  $FT(f)$
- scaling property is also valid for  $\text{III}$  function

# Sampling

**Notice:** The comb function density must be high enough to guarantee proper sampling

# Sampling

# Sampling

## Nyquist-Shannon theorem

Exact reconstruction of a continuous signal from its samples is possible if the signal is bandlimited and the sampling frequency is greater than twice the signal maximal frequency

Harry Nyquist (1889 – 1976) & Claude Elwood Shannon (1916 – 2001)

**Question:** How to use N-S theorem, if the original signal is unlimited?

# Sampling

## Common problems – aliasing

### The cause of aliasing:

when Nyquist-Shannon condition is broken, i.e.

- sampling frequency is not high enough or (time alias – wagon wheel effect)
- the signal is not bandlimited (PC games – far horizon)

# Sampling

## Common problems – aliasing

### How to eliminate aliasing?

- sampling at higher frequency
  - does it help if the signal is not band limited?
  - expensive for memory and time
- OR
- prefiltering
  - before sampling the input signal is “prefiltered” by lowpass filter

# Sampling

## Common problems – aliasing

### Some lowpass filters

- Gaussian filter

$$f_{\sigma}(x) = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{x^2}{2\sigma^2}}$$

- Sinc filter

$$f(x) = \frac{\sin(x)}{x}$$

- B-spline filter

$$b_1(x) = \begin{cases} 1 & |x| \leq 1/2 \\ 0 & |x| > 1/2 \end{cases}$$

$$b_n(x) = b_1(x) * b_1(x) * \dots * b_1(x) \quad \text{n-times}$$

# Reconstruction/Interpolation

Inverse process to sampling

**The purpose:** reconstruction of the original continuous signal from the sampled sequence.

**Reconstruction**  $\equiv$  convolution with a *low-pass* filter.

Common reconstruction filters:

- *box* (nearest neighbour)
- *tent* (linear interpolation)
- cubic B-spline (cubic polynomial interpolation)
- Gaussian
- *sinc* function
- Lanczos (windowed sinc function)

**Notice:** The unit area under the curve.

# Reconstruction/Interpolation

Lanczos filter

$$\text{lanczos3}(x) = \begin{cases} \frac{\sin \pi x}{\pi x} \frac{\sin \pi \frac{x}{3}}{\pi \frac{x}{3}} & |x| < 3 \\ 0 & |x| \geq 3 \end{cases}$$

# Reconstruction/Interpolation

Example

Box filter

# Reconstruction/Interpolation

Example

Tent filter

# Reconstruction/Interpolation

Example

Cubic B-spline filter

# Comb function

In 2D space

$$^2\text{III}(x, y) = \sum_{m=-\infty}^{\infty} \sum_{n=-\infty}^{\infty} \delta(x - m, y - n)$$

Separability of delta function implies:

$$^2\text{III}(x, y) = \text{III}(x)\text{III}(y)$$

# Sampling

Sampling in 2D:

- a process of converting a continuous 2D function into a discrete grid
- a multiplication with comb function:

$$^2\text{III}(x, y)f(x, y) = \sum_m \sum_n f(m, n)\delta(x - m, y - n)$$

Sampling in image domain

# Sampling

Common problems – aliasing

Insufficient sampling

Common problems – aliasing

## An example

# Sampling

Common problems – aliasing

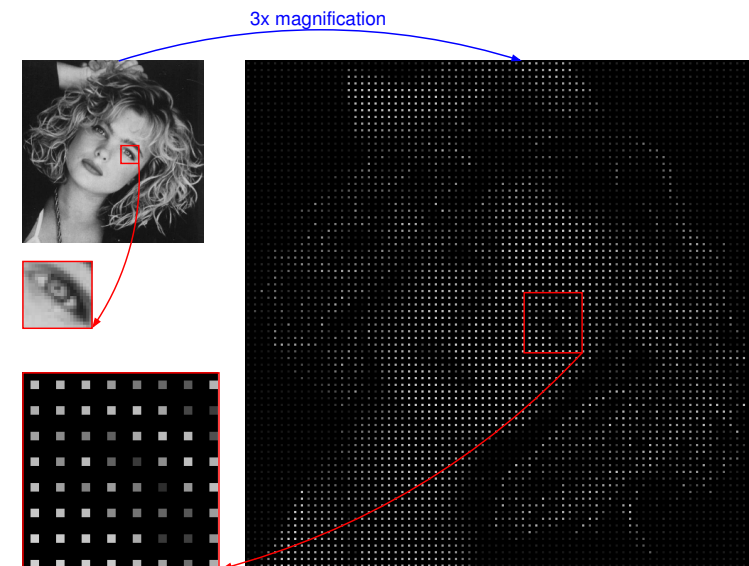

## An example

# Reconstruction/Interpolation

Task to solve

Problem of missing pixels when zooming into the digital image

## Reconstruction/Interpolation

Solution

### Nearest neighbour interpolation

$$Kernel_{3 \times 3} = \begin{bmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{bmatrix}$$

Note:  $Kernel_{3 \times 3} = [1 \ 1 \ 1]^T [1 \ 1 \ 1]$

## Reconstruction/Interpolation

Solution

### Completion of missing pixels (nearest neighbour)

3x magnification + nearest neighbour interpolation

## Reconstruction/Interpolation

Solution

### Bilinear interpolation

$$Kernel_{5 \times 5} = \frac{1}{9} \begin{bmatrix} 1 & 2 & 3 & 2 & 1 \\ 2 & 4 & 6 & 4 & 2 \\ 3 & 6 & 9 & 6 & 3 \\ 2 & 4 & 6 & 4 & 2 \\ 1 & 2 & 3 & 2 & 1 \end{bmatrix}$$

Note:  $Kernel_{5 \times 5} = \left(\frac{1}{3} [1 \ 2 \ 3 \ 2 \ 1]^T\right) \left(\frac{1}{3} [1 \ 2 \ 3 \ 2 \ 1]\right)$

## Reconstruction/Interpolation

Solution

### Completion of missing pixels (bilinear)

3x magnification + bilinear interpolation

# Resampling in 1D

## Let us design a 1D resampling filter

- The filter should be easy to implement and fast for computation.
- The filter should solve the alias problem.

# Resampling in 1D

## Design of the resampling filter

- ① reconstruct the continuous signal from the discrete one
- ② warp the domain of the continuous signal
- ③ prefilter the warped, continuous signal
- ④ sample this signal to produce the discrete output signal

# Resampling in 1D

## Important (implementation) notes

- During the resampling process we actually never construct a continuous signal  $h(u)$ ,  $h'(x)$  or  $h''(x)$ .
- We pick up the individual positions in the resampled image  $g(n)$  and look for their corresponding positions and their neighbourhood in the original image  $f(m)$ .
- As the computation is inverted, we never use  $\gamma$  function. We use only  $\gamma^{-1}$ .

# Resampling in 1D

## Derivation of an ideal resampling filter

### Computation of one sample point

$$\begin{aligned}
 g(n) &= h''(n) = \int h'(t)p(n-t)dt \\
 &= \int h(\gamma^{-1}(t))p(n-t)dt \\
 &= \int p(n-t) \sum_k f(k)r(\gamma^{-1}(t)-k)dt = \sum_k f(k)\rho(n,k)
 \end{aligned}$$

where

$$\rho(n,k) = \int p(n-t)r(\gamma^{-1}(t)-k)dt$$

- $\rho(n,k)$  is called a **resampling filter**.
- If  $\gamma$  is affine, we can derive:  $\rho(n,k) = p(\gamma^{-1}(n)-k) * r(\gamma^{-1}(n)-k)$ .

## Resampling in 1D

### Practical problems

- If the mapping  $\gamma$  is not affine, the filter  $\rho(n, k)$  is space variant.

### Solution (*postfiltering/supersampling*)

- ① Reconstruct the continuous signal from the discrete input signal.
- ② Warp the domain of the input signal.
- ③ Sample the warped signal at *very high resolution* to avoid alias.
- ④ Postfilter the signal to produce a lower resolution output signal.

**Notice:** The convolution is employed in the very end of this algorithm, i.e. it is discrete and space invariant.

## Resampling in 2D

### Task

### Design a 2D resampling filter

- Obey the rules that are valid for 1D resampling filter.
- The filter maps texels from texture space to screen space.
- The filter might be anisotropic.
- The filter should work fast.

## Resampling in 2D

### $\gamma$ -mapping

$\gamma^{-1}$  converts coordinates *from* screen space  $\mathbf{x} = (x, y)$   
*to* texture space  $\mathbf{u} = (u, v)$

## Resampling in 2D

### $\gamma$ -mapping

### $\gamma$ is projective

- circular neighbourhood of one pixel is transformed into an elliptical neighbourhood.
- can be locally approximated by linear mapping – Jacobian matrix  $J$ :

$$J^{-1} = \begin{bmatrix} \frac{\partial u}{\partial x} & \frac{\partial u}{\partial y} \\ \frac{\partial v}{\partial x} & \frac{\partial v}{\partial y} \end{bmatrix} = \begin{bmatrix} U_x & U_y \\ V_x & V_y \end{bmatrix}$$

$$\begin{aligned} \gamma : \mathbf{x} &= J\mathbf{u} \\ \gamma^{-1} : \mathbf{u} &= J^{-1}\mathbf{x} \end{aligned}$$

## Resampling in 2D

$\gamma$ -mapping

Gaussian warped by  $\gamma$  gives Gaussian:

$$\begin{aligned}
 g_I(\mathbf{u}) &= g_I(J^{-1}\mathbf{x}) \\
 &= \frac{1}{2\pi} e^{-\frac{1}{2}(J^{-1}\mathbf{x})^T J^{-1}\mathbf{x}} = \\
 &= \frac{1}{2\pi} e^{\frac{1}{2}\mathbf{x}^T (J^{-1T} J^{-1})\mathbf{x}} = \quad /V^{-1} = J^{-1T} J^{-1}/ \\
 &= |V|^{1/2} \cdot \frac{1}{2\pi|V|^{1/2}} e^{\frac{1}{2}\mathbf{x}^T V^{-1}\mathbf{x}} = \quad /|V|^{1/2} = |J|/ \\
 &= |J| \cdot g_V(\mathbf{x})
 \end{aligned}$$

where

- $J^{-1T} J^{-1}$  ... variance matrix (positive definite)
- standard multivariate Gaussian:

$$g_{\Sigma}(\mathbf{u}) = \frac{1}{2\pi|\Sigma|^{1/2}} e^{-\frac{1}{2}\mathbf{u}^T \Sigma^{-1}\mathbf{u}}$$

## Resampling in 2D

$\gamma$ -mapping

Formation of Gaussian regions

Variance matrix  $V$  defines a conic:

$$V^{-1} = \begin{pmatrix} A & B/2 \\ B/2 & C \end{pmatrix}^{-1} = J^{-1T} J^{-1}$$

from which the shape of zero-centered ellipse can be derived:

$$Q(u, v) = Au^2 + Buv + Cv^2 < F$$

Here

$$A = V_x^2 + V_y^2 + 1$$

$$B = -2(U_x V_x + U_y V_y)$$

$$C = U_x^2 + U_y^2 + 1$$

$$F = AC - \frac{B^2}{4}$$

## Resampling in 2D

$\gamma$ -mapping

Formation of Gaussian regions

$$\Sigma = \begin{bmatrix} 10^2 & 0 \\ 0 & 3^2 \end{bmatrix}$$

$$\Sigma = \begin{bmatrix} 10^2 & 20 \\ 20 & 3^2 \end{bmatrix}$$

## Resampling in 2D

$\gamma$ -mapping

BoundingBox for elliptical regions

$$\begin{aligned}
 u &= \pm 2\sqrt{\frac{CF}{4AC - B^2}} \\
 v &= \pm 2\sqrt{\frac{AF}{4AC - B^2}}
 \end{aligned}$$

Weight for a particular texture pixel

$$\begin{aligned}
 \text{weight}(u, v) &= \quad / \rho((x, y), (u, v)) / \\
 &= e^{-\alpha Q(u, v)}
 \end{aligned}$$

Notice:  $\alpha$  ... user defined constant (e.g.  $\alpha = 2$ )

## Resampling in 2D

$\gamma$ -mapping

### Image Pyramids (MIP map)

- Size of ellipse determines level of detail in MIP map pyramid that should be fetched from the memory.
- MIP map pyramid is precomputed to avoid (pointless) repetitive downsampling.

## Resampling in 2D

Elliptical Weighted Average (EWA)

### Implementation Notes

For each image pixel  $(x,y)$  from screen space:

- ① Find corresponding point  $(u,v)$  in texture space.
- ② Define the local affine transform  $\gamma$ .
- ③ Compute Jacobian  $J$  of this mapping.
- ④ Delineate the ellipse in texture space (find bounding box)
- ⑤ Using the ellipse size choose the two nearest MIP map levels
- ⑥ Perform the following steps in each MIP map level and combine the results
  - ① Build the Gaussian over the texture.
  - ② Evaluate direct convolution of texture image with Gaussian.
  - ③ Get one value as a result.
- ⑦ Store the result (one value) in the screen pixel  $(x,y)$ .

## You should know the answers . . .

- Show that the 2D DFT is separable transform.
- Derive the complexity of 2D discrete FFT.
- Explain the reciprocity of wide and narrow shapes in time and frequency domain, respectively.
- Derive (do not formulate) the Nyquist-Shannon theorem for 2D image data.
- Show an example of the aliasing effect.
- What is a prefilter?
- What is the difference between a screen space and texture space?
- Give an example of  $\gamma$  warping function both for 1D and 2D case.
- What is the difference between projective and affine mappings?
- Describe individual steps of EWA filter.
