The Economics of Energy Corporations (2)

## **Homework Question**

- Look at the CCGT power station model we created
- Assume that the capex and opex calculations remain the same
- Change the following assumptions:
  - Capacity 1000MW
  - Gas price is \$2.00/mmbtu
  - Electricity price is €45/MWh
  - Load factor is 80%
  - Carbon price is €40/tonne
  - Corporate Tax is 20%
  - Efficiency is 54%
- For the WACC assume that the debt:equity split is 80:20, change the interest rate to 3.5% and the Beta to 0.9

- 1. What is the WACC for the project?
- 2. What is the NPV of the project, and what is the IRR? What is the payback period?
- 3. What is the breakeven electricity price for the project?
- 4. What is the breakeven gas price for the model?
- 5. In one paragraph, describe the key features of the investment and whether you would recommend it to your management
  - 1. Remember to mention some other key assumptions

- Questions on sensitivity
  - What happens if the gas price doubles?
  - What electricity price is needed for the project to breakeven if the load factor falls to 20% (assume gas price of USS\$2.00/mmbtu again)
  - If the carbon price doubles, what electricity price is needed to allow the project to breakeven (load factor back to 80%)?
  - If the load factor falls to 10% what capacity payment would you ask for?
- Please send me your model so I can see your workings
- Please write answers in a Word or Pages document and use graphs where appropriate
