Endodontics

**Pulp and periodontal diseases –
diagnosis, therapy, prevention**

Aim of endodontic treatment

Healing of pulp diseases or removal
bacteria from the root canal system
and regeneration of damaged periodontal
tissues. (Canal shaping, cleaning and filling)

,, Endodontist helps nature only “

Meyers conclusions

- The root canal is not round but oval (long axis mesiodistal)
- The root canal does not go straight but it deflects distal
- The outfall is not on the top of the root but below (distal or distooral)

Meyer's conclusions

- The walls of the root canal between apical constriction to apical foramen are divergent
- The root canal system has usually more outfalls (ramifications)
- The ramifications are situated mostly in apical area (first apical mm)
- All foramina are situated in cementum

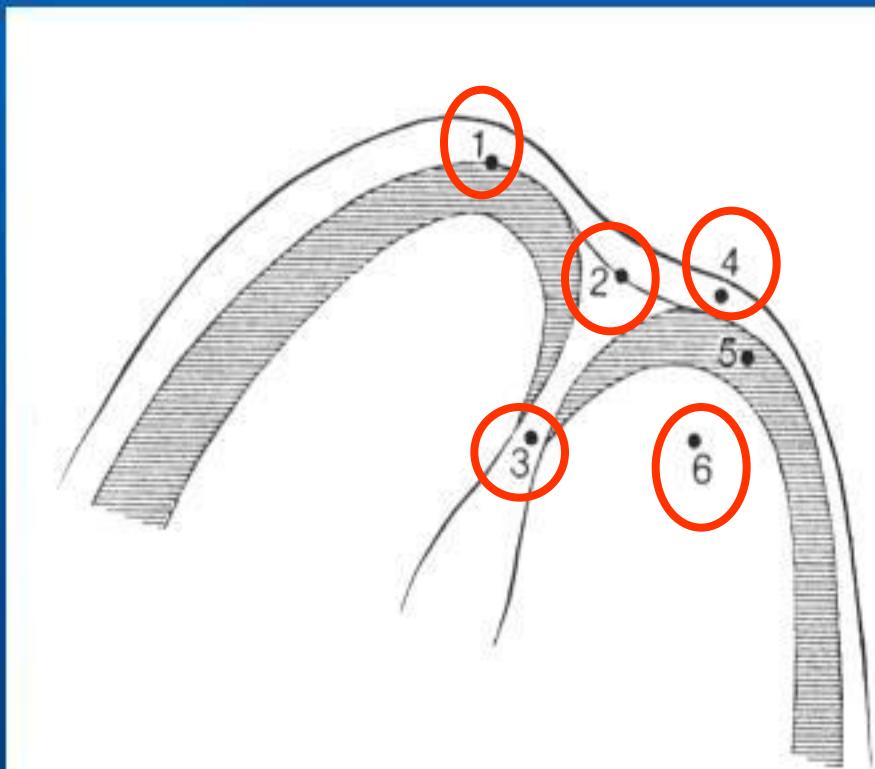

Basic forms of the root canal systém (Weine)

Apical morphology

1. X – ray apex
2. Foramen apicale
3. Apical constriction
4. Periodontal ligament
5. Root cementum
6. Dentin

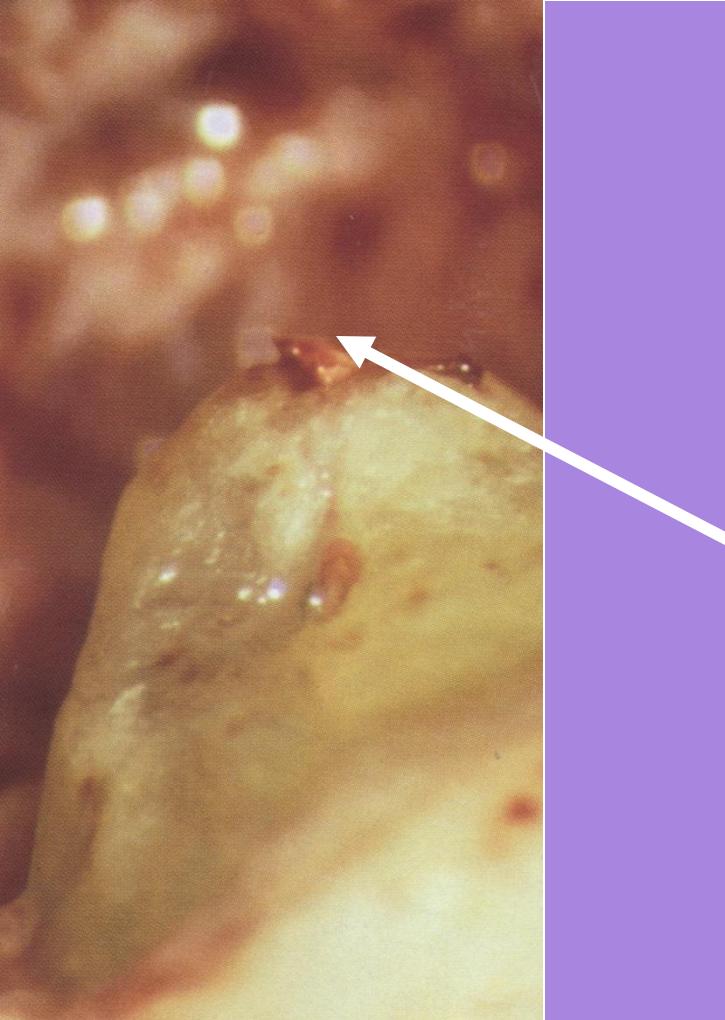

Canal shaping terminates in apical constriction

- Small communication
- Less risk of periodontal damage
- Prevention of overfilling
- Prevention of apical transport of infectious material
- Possibility of good bacterial decontamination
- Possibility of good condensation of the root filling

The diagram illustrates the configuration of apical constriction in a developing embryo. It features a central dark blue rectangular area representing the germ ring, surrounded by eight yellow, elongated, and slightly curved structures representing the germinal cells. Four white arrows point from the text "Configuration of apical constriction" towards the top and bottom edges of the central blue area, indicating the site of apical constriction.

Configuration of apical constriction

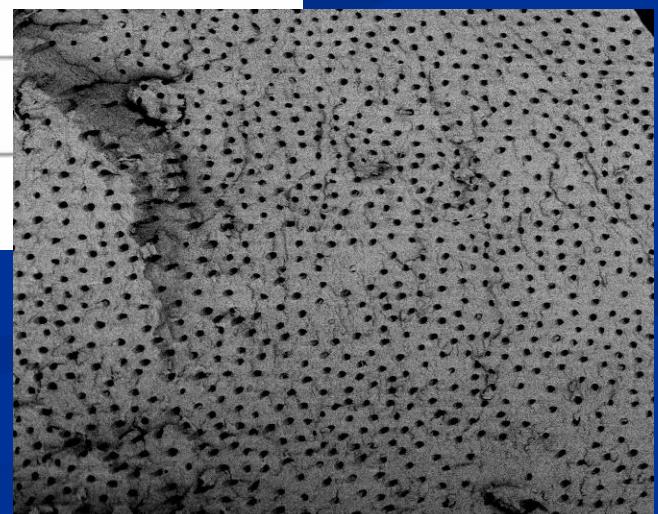

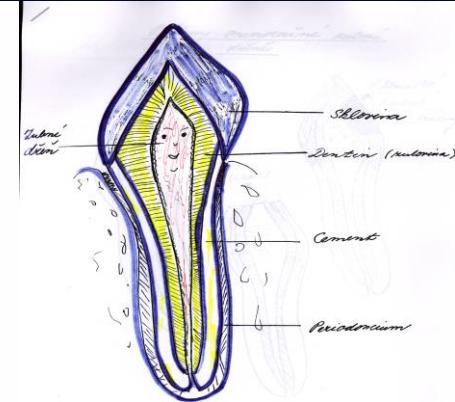

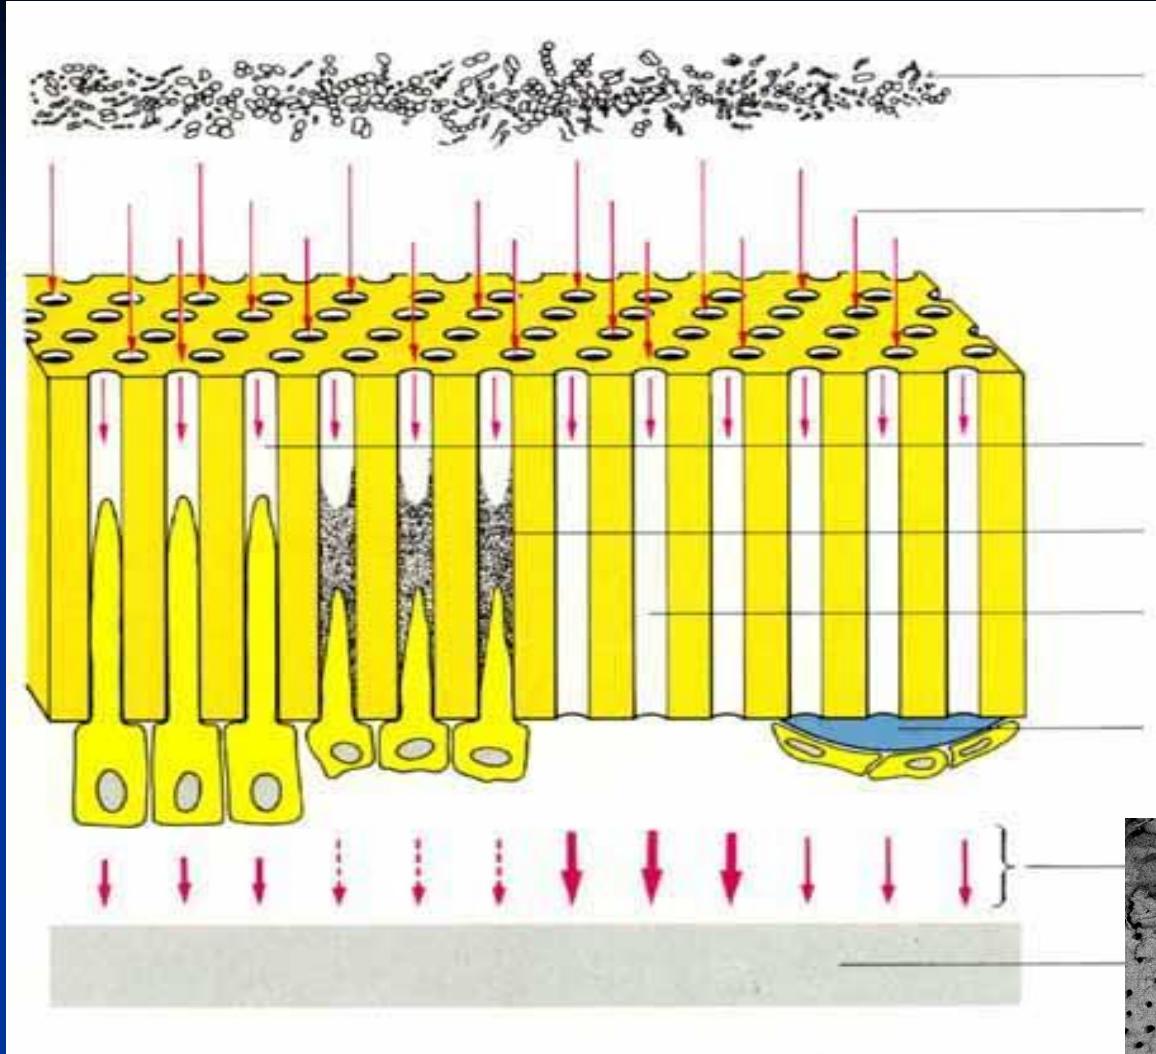

Real situation

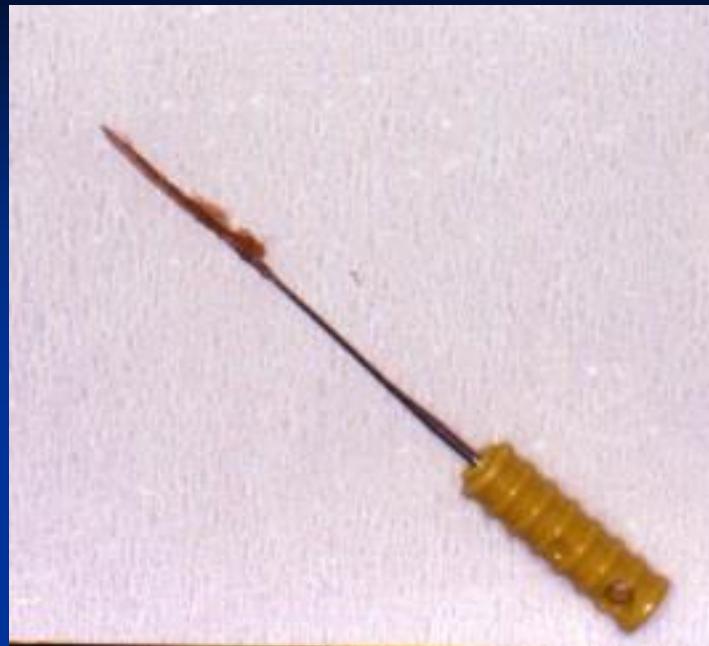

X- ray apex

- Macrocanal system
- Microcanal system

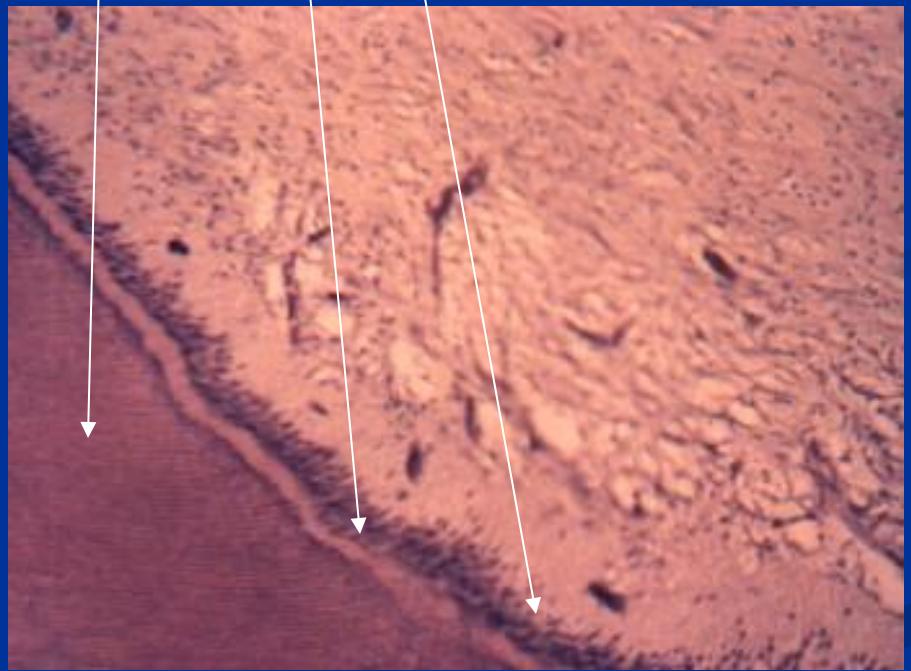

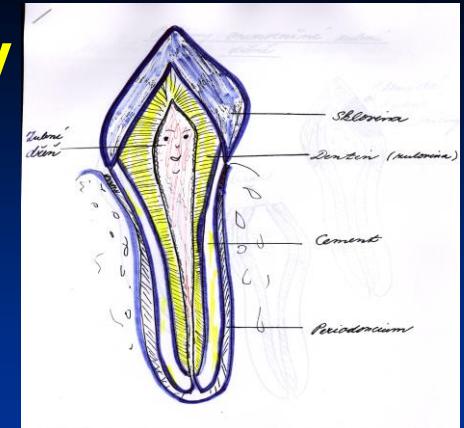

**Endodont: dentin and pulp
(morphological and functional unit)**

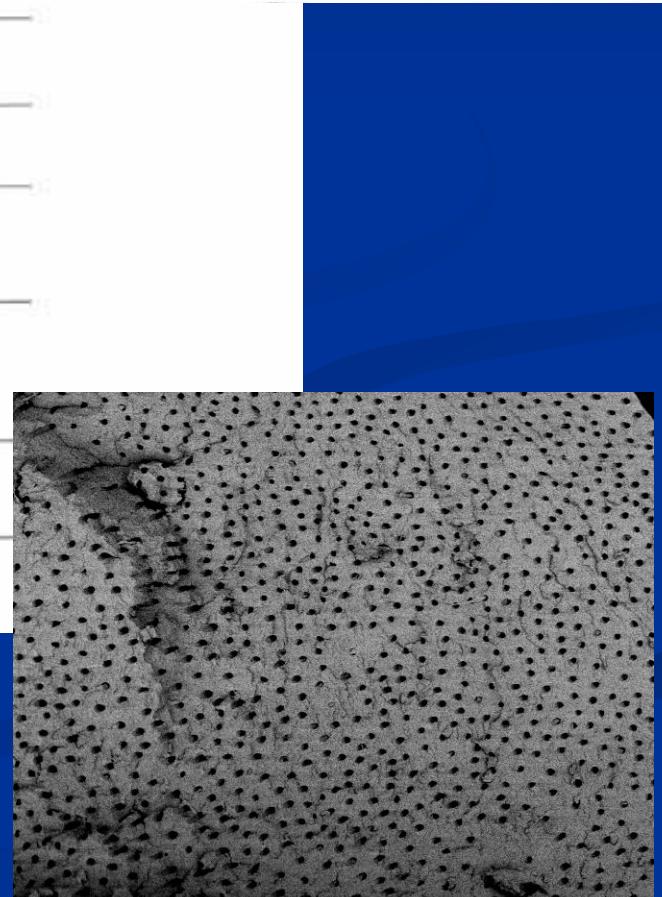

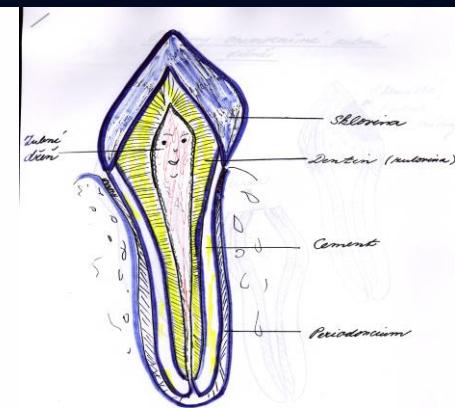

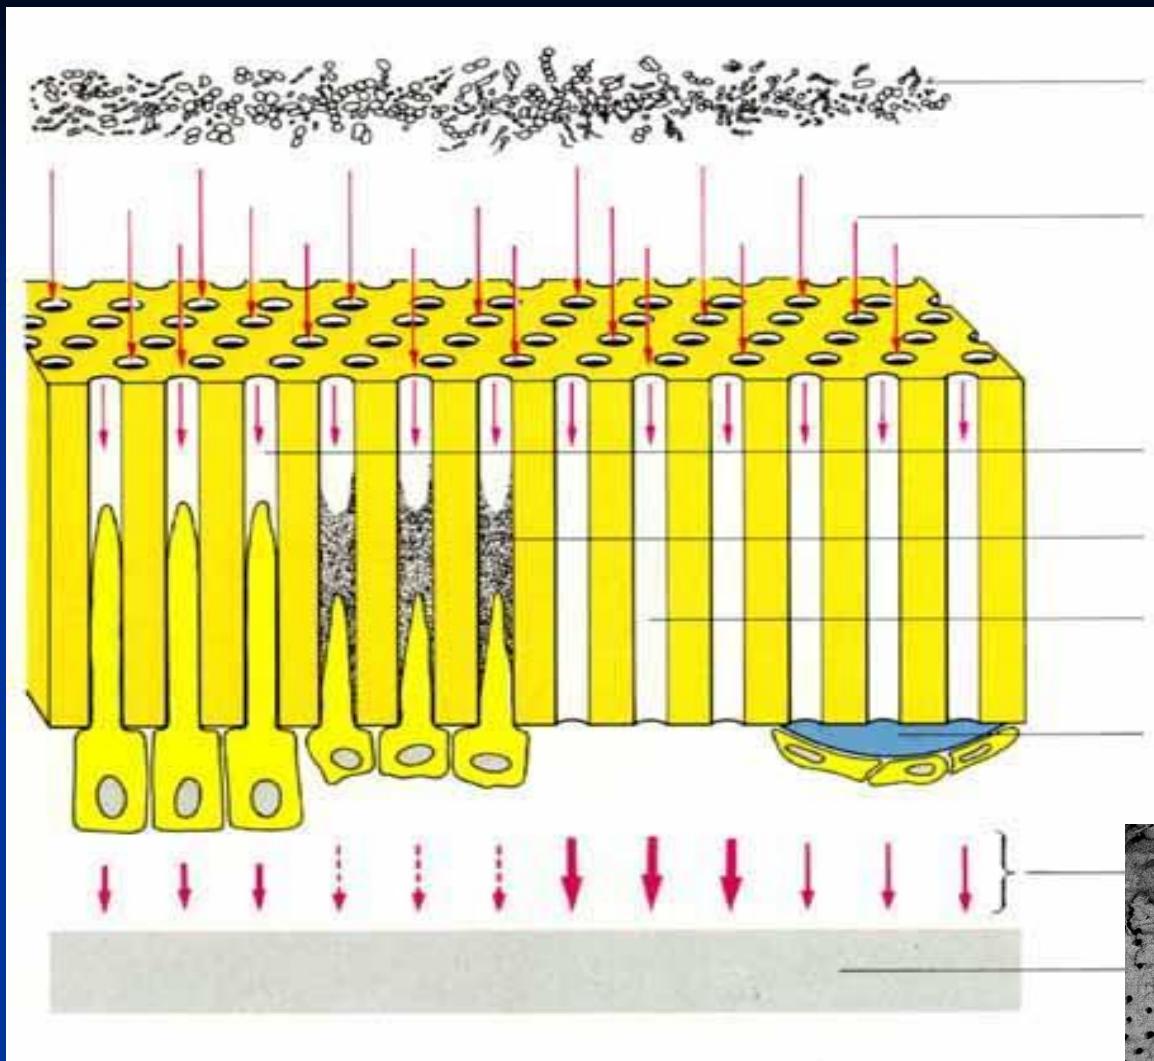

Dental pulp

Odontoblasty
Predentin
Dentin

Defense mechanisms of the pulp

- Sclerosis
- Tertiär dentin
- Dentin bridge

Pulpodentinální orgán - endodont

Pulp diseases

Inflammation - pulpitis

Consequences

- Necrosis
- Gangraena
- Apical periodontitis

Reasons

- Bacteria
- Mechanical irritants (overinstrumentation, trauma)
- Chemické (esp. phenolic based intracanal medicaments, overfilling, irrigants)

Classification of pulp diseases

■ Histopathological

Hyperemia pulpae

**Pulpitis acuta serosa partialis
totalis**

**Pulpitis acuta purulenta partialis
totalis**

Classification of pulp diseases

■ Histopathological

Pulpitis chronica clausa

aperta

ulcerosa

polyposa

Classification of pulp diseases

Clinical

Reversible pulpitis

Pain does not linger after stimulus is removed

Pain is difficult to localize

Normal periradicular appearance

Teeth are not tender to percussion

Classification of pulp diseases

Clinical

Irreversible pulpitis

Pain may develop spontaneously or from stimuli

In later stages heat is more significant

Response lasts from minutes to hours

When the periodontal ligament is involved, the pain is localized

A widened periodontal ligament may be seen in later stages

Relief (analgetics, antibiotics, sipping cold drinks)

Diagnosis

Clinical examination

**Extraoral (swelling, redness, extraoral sinuses,
lymph nodes, degree of mouth opening)**

Intraoral examination

**Swelling, redness, palpation, percussion, sinus
tract examination, teeth mobility, pockets**

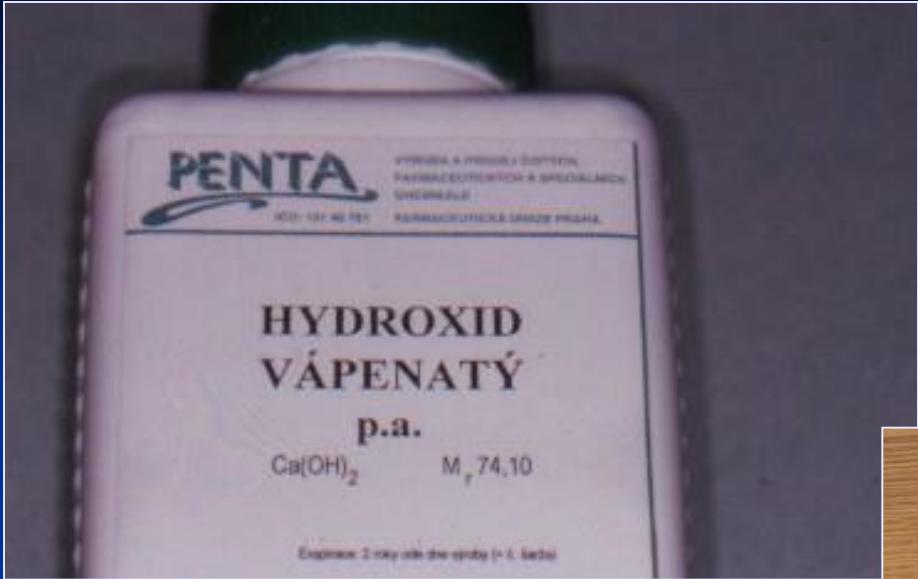

Diagnosis

Clinical examination

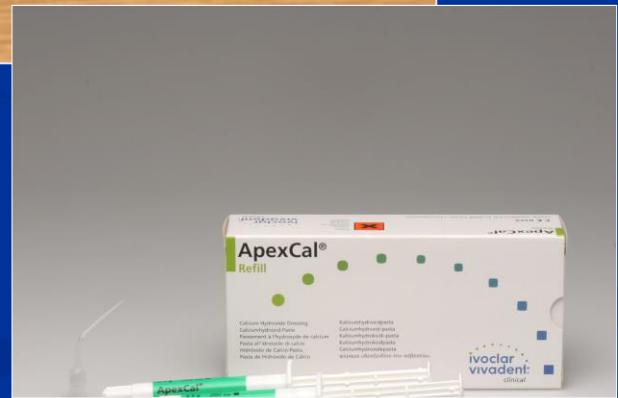

Pulp sensitivity tests, radiographic
examination, transillumination.

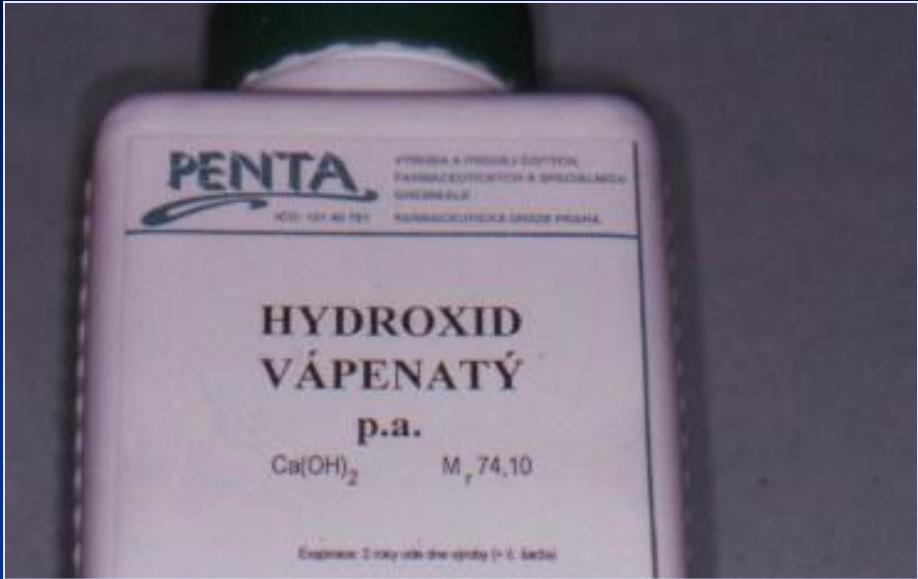

A photograph of a pond in winter. The water is dark and reflects the surrounding environment. A thin layer of ice covers the surface, with some ducks swimming and others standing on the ice. Bare trees are visible along the shoreline in the background.
