## Matter and Energy

>Everything is made up of basic particles of matter and fields of energy / force, which also means that the fundamental structural elements of the organic and inorganic world are identical.
$>$ Living matter differs from non-living matter mainly by its much higher level of organisation.

## Elementary Particles of Matter

(i.e. having - probably - no internal structure)
>, „force" particles - integer spin - bosons
$>$ Vector bosons - spin 1
Foton
Gluons
W, Z (week bosons)
Graviton
>Scalar boson - spin 0
>Higgs boson
„matter" particles - noninteger (odd) spin - fermions
$>$ The elementary particles of matter are leptons and quarks
$>$ Leptons - electrons, muons, neutrinos and their anti-particles - light particles without internal structure
$>$ Quarks (u, c, t, d, s, b) - heavier particles without internal structure

## Composite particles

$>$ Hadrons - heavy particles formed of quarks - baryons (fermions - proton (u, u, d), neutron (d, d, u)) mezons (bosons (quark-antiqvark))

## The Four Fundamental Energy / Force Fields

strong

weak
Strong : weak : electromagnetic : gravitational force - $1: 10^{-5}: 10^{-2}: 10^{-39}$ at interaction distance of about $10^{-24} \mathrm{~m} ; 10^{-7}: \sim 0: 10^{-9}: 10^{-46}$ at a distance of about $10^{-18} \mathrm{~m}(1 / 1000$ of atom nucleus dimension). In the distance equal to nucleus dimension goes to zero also strong interaction.

## Photons

$>$ Photons - energy quanta of electromagnetic field, zero mass
$>$ Energy of (one) photon: $E=h f=h c / \lambda$ $h$ is the Planck constant $\left(6.62 \cdot 10^{-34} \mathrm{~J} \cdot \mathrm{~s}\right)$, $f$ is the frequency, $c$ is speed of light in vacuum, $\lambda$ is the wavelength.

## Particles and Field Energy Quanta

Particles of matter and field energy quanta are capable of mutual transformation (e.g., an electron and positron transform to two gamma photons in the so-called annihilation - this is used in PET imaging).

## Quantum Mechanics

The behaviors of ensembles of a given type of particle obey equations which are similar to wave equations.

On the left pattern formed on a photographic plate by an ensemble of electrons hitting a crystal lattice. Notice that it is very similar to the diffraction pattern produced by a light wave passed through optical grating.

## Quantum Mechanics

## tunnel effect:

## In classical dynamics, <br> A stops at B and cannot go any higher

In classical dynamics,
A stops at B and cannot go any higher

In quantum mechanics,
A borrows energy and can cross (from B to C)
to the other side of the mountain

## Quantum Mechanics: Heisenberg uncertainty relations

$$
\begin{aligned}
& \delta r \cdot \delta p \geq h / 2 \pi \\
& \delta E \cdot \delta t \geq h / 2 \pi
\end{aligned}
$$

The position $r$ and momentum $p$ of a particle cannot be simultaneously measured with independent precision (if the uncertainty of particle position - $\delta r-$ is made smaller, the uncertainty of particle momentum - $\delta p-$ automatically increases). The same holds for the simultaneous measurement of energy change $\delta E$ and the time $\delta t$ necessary for this change. $h$ is the Planck constant.

## Schrödinger equation

(to admire ©)

> second derivative
> "one-dimensional" S. equation

Radial coordinates of an electron in a hydrogen atom
S. equation for the electron in the hydrogen atom

## Solution of the Schrödinger Equation

$>$ The solution of the Schrödinger equation for the electron in the hydrogen atom leads to the values of the energies of the orbital electron.
$>$ The solution of the Schrödinger equation often leads to numerical coefficients which determine the possible values of energy. These numerical coefficients are called quantum numbers

## Quantum numbers for Hydrogen

$>$ Principal $\mathrm{n}=1,2,3 \ldots(\mathrm{~K}, \mathrm{~L}, \mathrm{M}, \ldots$.
$>$ Orbital for each $\mathrm{n} \quad \mathrm{I}=0,1,2, \ldots \mathrm{n}-1(\mathrm{~s}, \mathrm{p}, \mathrm{d}, \mathrm{f} \ldots$ ) $>$ Magnetic for each I $\quad \mathbf{m}=0,1,2, \ldots$ । $>$ Spin magnetic for each $\mathrm{m} \mathbf{s}=1 / 2$
>Pauli exclusion principle - in one atomic electron shell there cannot be present two or more electrons with the same set of quantum numbers.

## Ionisation of Atoms

The binding energy of an electron $E_{b}$ is the energy that would be required to liberate the electron from its atom - depends mainly on the principal quantum number.

```
excitation
```

Example of ionisation: photoelectric effect

$$
h \cdot f=E_{b}+1 / 2 m \cdot \cdot v^{2}
$$

## Emission Spectra

slits prism \(\left.\begin{array}{l}Visible emission <br>
spectrum of <br>

hydrogen.\end{array}\right\}\)| modro- $=$ |
| :--- |
| bluish |
| Learn the Czech |
| names of |
| colours :-) |
|  |

```
Hydrogen
discharge tube
```

Dexcitations between discrete energy levels result in emitted photons with only certain discrete energies, i.e. radiation of certain frequencies/wavelengths.

## Excitation <br> of <br> electrons <br> Emission of light

## Hydrogen spectrum again

## magenta, cyan and red line

according
http://cwx.prenhall.com/book bind/pubbooks/hillchem3/me dialib/media_portfolio/text_i mages/CH07/FG07_19.JPG

## Excitation (absorption) Spectra for Atoms

Absorption lines in visible spectrum of sun light.
Wavelengths are given in Angströms $(\AA)=0.1 \mathrm{~nm}$
http://cwx.prenhall.com/bookbind/pubbooks/hillchem3/medialib/media_portfolio/07.html

Transitions between discrete energy states of atoms!!

## Excitation (Absorption) Spectrum for Molecules

Absorption spectrum of a dye

## Atom nucleus

Proton (atomic) number - $Z$
Nucleon (mass) number - $A$
Neutron number $-N \quad N=A-Z$

Atomic mass unit $u=1.66 \cdot 10^{-27} \mathrm{~kg}$, i.e. the $1 / 12$ of the carbon C-12 atom mass

Electric charge of the nucleus $Q=Z 1.602 \cdot 10^{-19} \mathrm{C}$
If relative mass of electron $=1$
$\Rightarrow$ Relative mass of proton $=1836$
$\Rightarrow$ Relative mass of neutron $=1839$

## Mass defect of nucleus

$=$ measure of nucleus stability:

$$
\delta m=\left(Z m_{p}+N m_{n}\right)-m_{n u c}
$$

http://cwx.prenhall.com/bookbind/pubbooks/hil Ichem3/medialib/media_portfolio/text_images/ CH19/FG19_06.JPG
$\mathrm{E}=\delta \mathrm{m} . \mathrm{c}^{2}$
This formula allows to calculate amount of energy liberated during the synthesis of the nucleus.

## Nuclides

$>$ nuclide - a nucleus with a given $A, Z$ and energy
>Isotopes - nuclides with same $Z$ but different $A$
>Isobars - nuclides with same A but different Z
$>$ Isomers - nuclides with same $Z$ and $A$, but different energy (e.g., $\mathrm{Tc}^{99 \mathrm{~m}}$ used in gamma camera imaging)

## Isotope composition of mercury <br> $\%$ of Hg atoms vs. isotope nucleon number ( A )

## What else is necessary to know?

>Radionuclides - nuclides capable of radioactive decay
$>$ Nuclear spin:
Nuclei have a property called spin. If the value of the spin is not zero the nuclei have a magnetic moment i.e, they behave like small magnets - NMR - nuclear magnetic resonance spectroscopy and magnetic resonance imaging (MRI) in radiology are based on this property.
