#### Nanostructural Materials

"Prey", the latest novel by Michael Crichton, author of "Jurassic Park".

The horrible beasties threatening humanity in this new thriller are not giant dinosaurs, but swarms of minute "nanobots" that can invade and take control of human bodies.

Last summer, a report issued by a Canadian environmental body called the action group on erosion, technology and concentration took a swipe at nanotechnology. It urged a ban on the manufacture of new nanomaterials until their environmental impact had been assessed. The group is better known for successfully campaigning against biotechnology, and especially against genetically modified crops.

The research, led by a group at the National Aeronautics and Space Administration's Johnson Space Centre in Houston, has found in preliminary studies that inhaling vast amounts of nanotubes is dangerous. Since they are, in essence, a form of soot, this is not surprising. But as most applications embed nanotubes in other materials, they pose little risk in reality.

#### **Room at the Bottom**

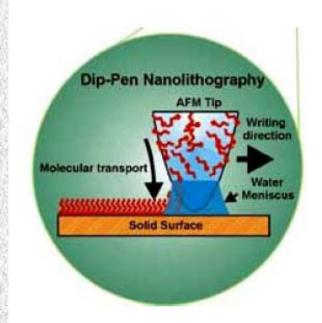

What I want to talk about is the problem of manipulating and controlling things on a small scale ...

As soon as I mention this, people tell me about miniaturization, and how far it has progressed today. They tell me about electric motors that are the size of the nail on your small finger. And there is a device on the market, they tell me, by which you can write the Lord's Prayer on the head of a pin. But that's nothing; that's the most primitive, halting step in the direction I intend to discuss. It's a staggeringly small world that is below. In the year 2000, when they look back at this age, they will wonder why it was not until the year 1960 that anybody began seriously to move in this direction......

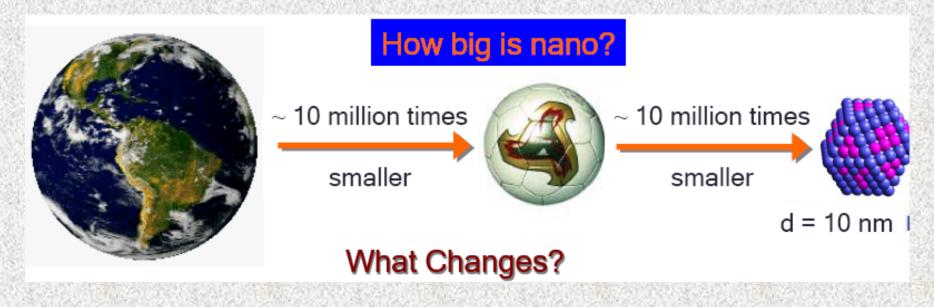

Prof. Richard Feynman in "There's plenty of room at the bottom", lecture delivered at the annual meeting of the APS, Caltech, 29 December, 1959.

# **Nanoscale Writing**

Nanoscale writing with an AFM (Mirkin et al.)

As soon as I mention this, people tell me about miniaturization, and how for it has progressed today. They tell me about electric motors that are the size of the not on your small finger. And there is a device on the market. they tell me, by which you can write the Land's Prayer on the head of a pin. But that's nothing! that's the most primitive, halting step in the direction I intend to discuss. It is a staggeringly small world that is below. In the year 2000, when they look back at this age, they will wonder why it was not until the year 1950 that anybody began seriously to move in this direction. Richard P. Feynman, 1960

Size is another variable to change physical and chemical properties

Each physical property or fenomenon has a characteristic length

When particle size is comparable to the characteristic length, property start to depend on the start to depend on

Negligible light scattering - New optics

Quantum size effects - Information technology, Storage media

High surface area - Catalysts, Adsorbents

Large interfacial area - New composites

Surface modifications - Targeted drug delivery

Nanoscale regime Size 1-100 nm (traditional materials > 1  $\mu$ m)

Physical and chemical properties depend on the size !!

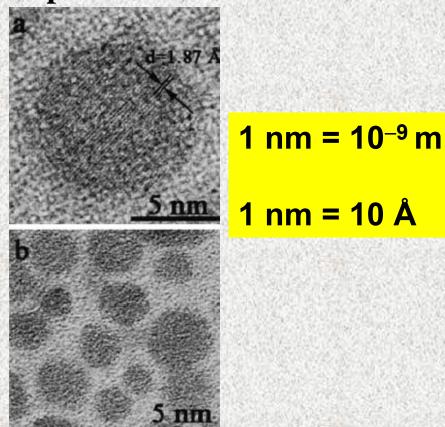

#### **Natural examples:**

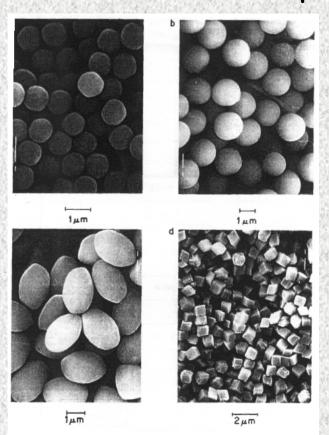

- Human teeth, 1-2 nm fibrils of hydroxyapatite  $Ca_5(PO_4)_3(OH)$  + collagen
- Asbestos, opals, calcedon
- Primitive meteorites, 5 nm C or SiC, early age of the Solar system

Nanoscale objects have been around us, but only now we can observe them, manipulate and synthesize them.

# Nanoparticles 1 – 100 nm

## Traditional materials $> 1 \mu m$

#### **CARBON NANOTUBES**

A single-shell nanotube image (Source from Dr. P. M. Ajayan)

A multi-shell nanotube image (Ebbesen, T. W., 1994. Anniv. Rev. Mater. Sci. 24:235-64. courtesy of NEC/Handa)

- 1. A unique species somewhere between traditional carbon fibers and nevel forms of carbon such as fullerenes.
- 2. A seamless cylindrical sheet of graphite whose diameter is so small and its aspect ratio (diameter vs. length) is so great that it can be considered from the electronic point of view as a one-dimensional structure.

There are two sorts of carbon nanotubes. One is multi-shell nanotubes and the other is single-shell nanotubes. The former have two or more layers such as the left-side figure below and about 2 to 20 nm diameter while the letter have only one layer and about 4 to 2 nm diameter. Both are a few tens of microns long. In multi-shell nanotubes, the inter layer spacing is ~0.34 nm. In both cases, each carbon atom is completely bonded to neighboring carbon atoms through sp<sup>2</sup> hybridization to form a seamless shell, in the absence of external strain, carbon nanotubes are always straight unless carbon rings having a number of carbons deflant from six (pentagons, heptagons, octagons, etc.) are present in the hexagonal network.

A ploture of a typical multi-shell nanotube taken using TEM (Source from Dr. P. M. Ajayas)

- Graphene
- SAM

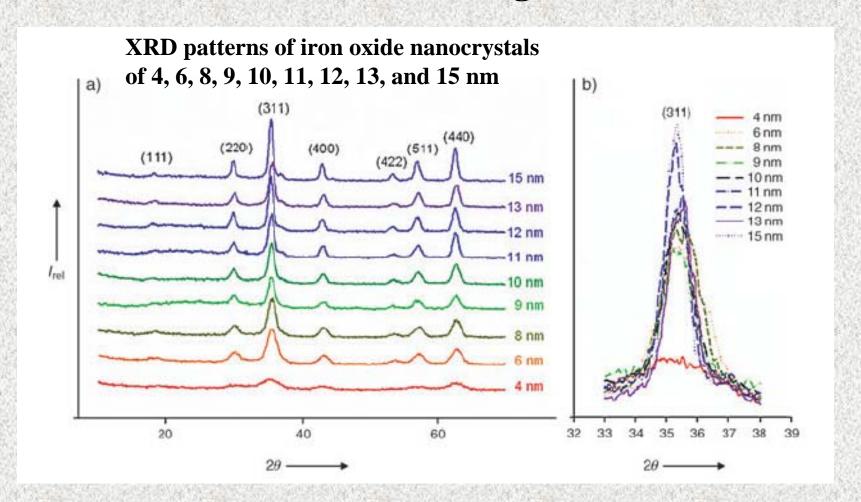

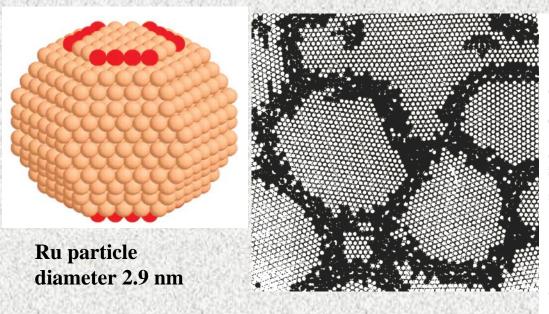

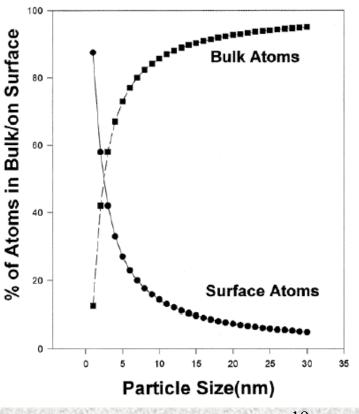

# **Coherence Length**

Decreasing grain size = Increasing volume fraction of grain boundaries (50% for 3 nm particles)

Nanomaterials

19

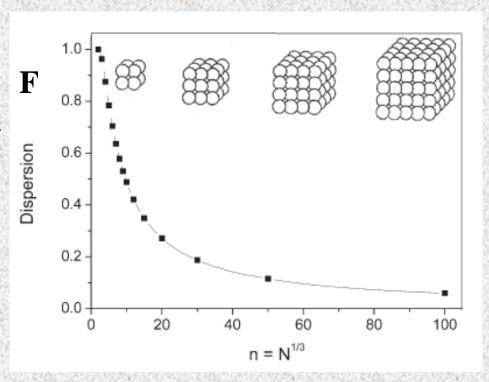

Dispersion F = the fraction of atoms at the surface

F is proportional to surface area divided by volume

N = total number of atoms

$$V \sim r^3 \sim N$$

$$F \approx \frac{r^2}{r^3} \approx \frac{1}{r} \approx \frac{1}{\sqrt[3]{N}}$$

n = number of atoms at the cube edge

**Properties of grain boundaries** 

- **▶** Lower coordination number of atoms
- ➤ Reduced atomic density (by 10 30 %)
- **▶**Broad spectrum of interatomic distances

#### **Experimental evidence**

- >HREM
- **EXAFS**, reduced number of nearest and next-nearest neighbors
- > Raman spectroscopy
- ➤ Mössbauer spectroscopy, quadrupole splitting distribution broadened
- **▶**Diffusivity enhanced by up to 20 orders of magnitude !!
- **➤**Solute solubility in the boundary region

Ag (fcc) and Fe (bcc) immiscible in (s) or (l), but do form solid solution as nanocrystalline alloy

>EPR, nano-Si gives a sharp signal Nanomaterials

Atoms at surfaces have fewer neighbours than atoms in the bulk

Lower coordination and unsatisfied bonds surface atoms are less stabilized than bulk atoms

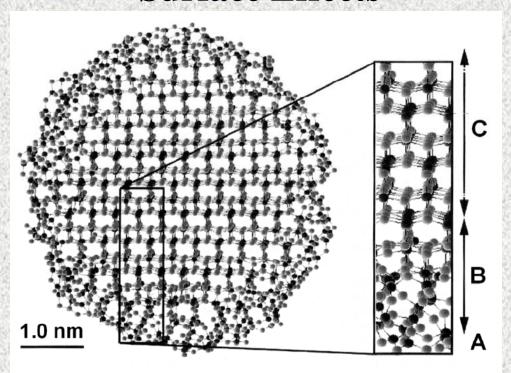

The smaller a particle the larger the fraction of atoms at the surface, and the higher the average binding energy per atom

The melting and other phase transition temperatures scale with surfaceto-volume ratio and with the inverse size

**Example: the melting point depression in nanocrystals** 

2.5 nm Au particles 930 K

bulk Au 1336 K

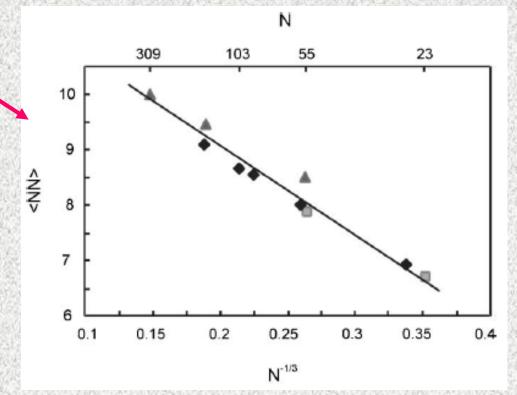

A = Atoms at surfaces (one layer) – fewer neighbours, lower coordination, unsatisfied (dangling) bonds

B = Atoms close to surface (several layers) – deformation of coordination sphere, distorted bond distances and angles

C = Bulk atoms – not present in particles below 2 nm

#### coordination number

#### **Surface Effects**

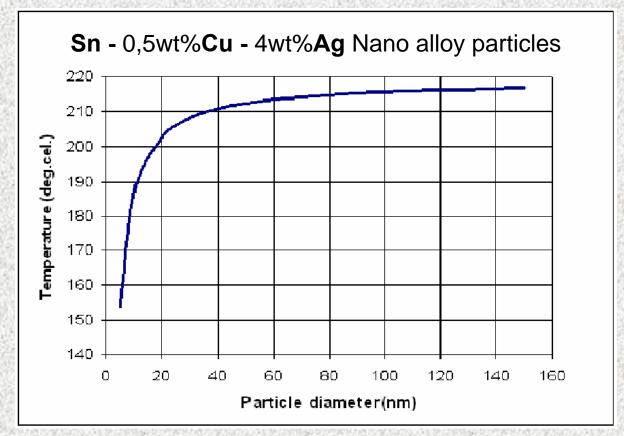

Calculated mean coordination number <NN> as a function of inverse radius, represented by N $^{-1/3}$  for Mg clusters (triangles = icosahedra, squares = decahedra, diamonds = hcp

Atom binding (vaporization) energies lower in nanoparticles, fewer neighbors to keep atoms from escaping

Plasticity of nanocrystalline ceramics

# **Melting Point Depression**

$$\Delta T = T_m^{bulk} - T_m(r) = \frac{2T_m^{bulk}}{H_m^{bulk} \rho_s r} \left[ \sigma_s - \sigma_L \left( \frac{\rho_s}{\rho_L} \right)^{\frac{2}{3}} \right]$$

# Gibbs-Thomson Equation

$$\frac{T_m(r) - T_m^{bulk}}{T_m^{bulk}} = -\frac{2V_{mol}^l \gamma_{sl}}{\Delta H_m r}$$

In nanoparticles confined in pores

 $T_m(r) = mp$  of the cluster with radius r

 $T_m^{bulk} = mp$  of the bulk

 $V_{mol}^{l}$  = the molar volume of the liquid

 $\gamma_{sl}$  = the interfacial tension between the s and l surface

 $\Delta H_m^{bulk}$  = the bulk latent heat of melting

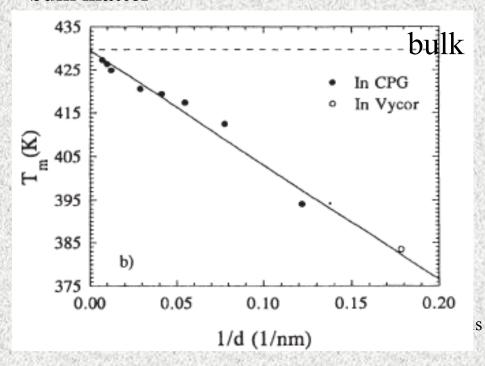

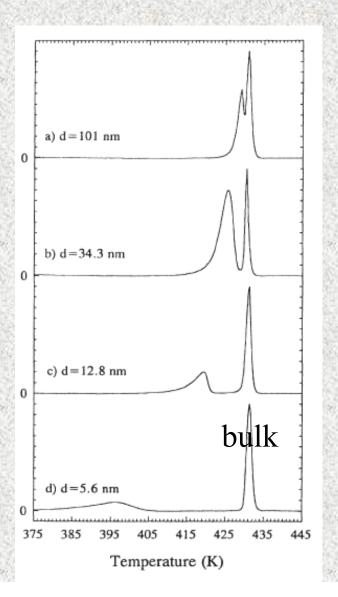

#### **Phase Transitions**

**Phase transitions = collective phenomena** 

With a lower number of atoms in a cluster a phase transition is less well defined and broadened

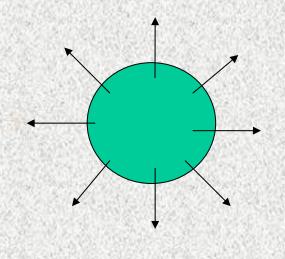

Small clusters behave more like molecules than as bulk matter

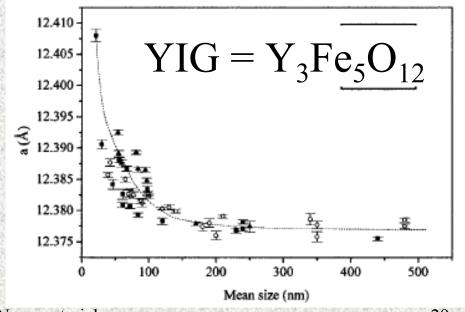

# Reduction in particle size

- metal particles usually exhibit a lattice contraction
- oxide particles exhibit a lattice expansion

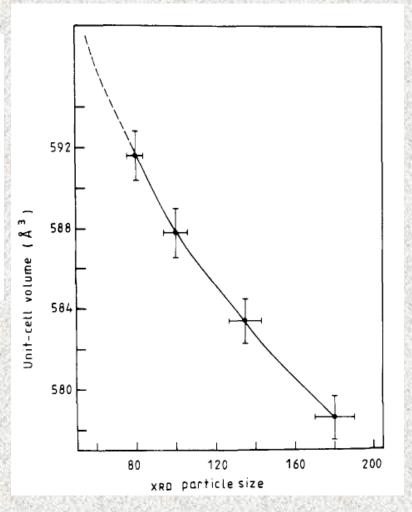

Nanomaterials

29

Correlation between the unitcell volume (cubic) and the XRD particle size in  $\gamma$ -Fe<sub>2</sub>O<sub>3</sub> nanoparticles

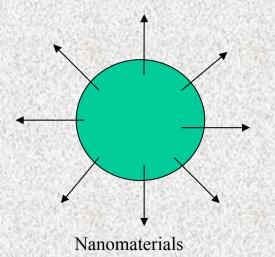

The smaller the particle size the larger the unit cell volume.

The inter-ionic bonding in nanoparticles has a directional character ions in the outermost layer of unit cells possess unpaired electronic orbitals

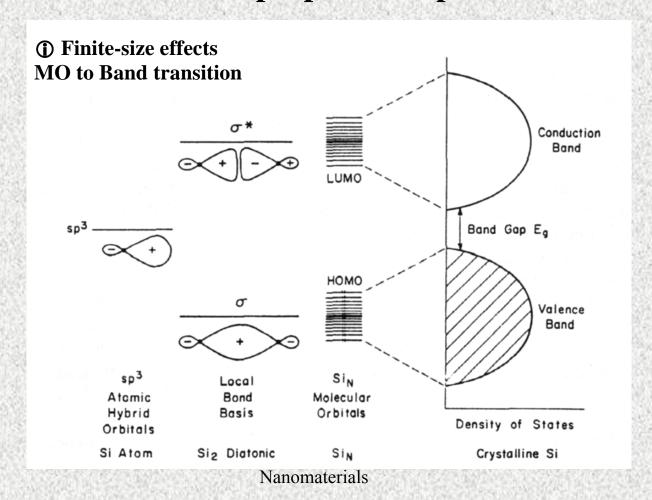

Associated electric dipole moments, aligned roughly parallel to each other point outwards from the surface

The repulsive dipolar interactions increase in smaller particles reduced by allowing unit cell volume to increase

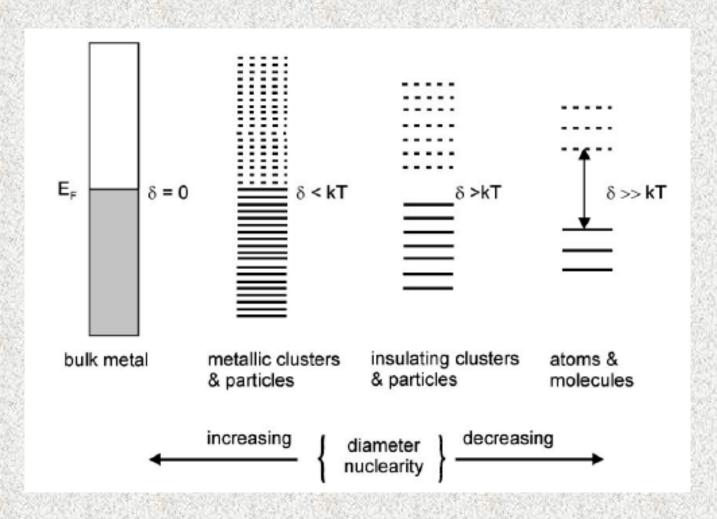

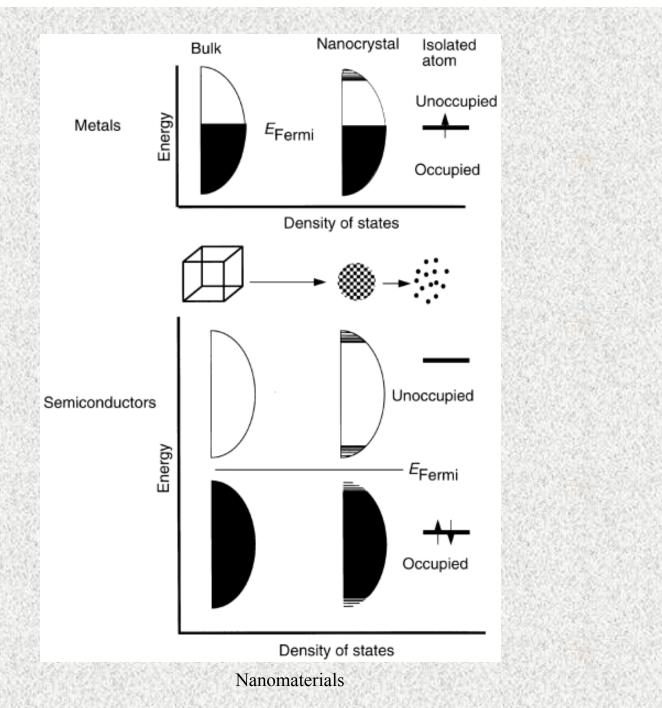

# **Quantum Confinement Effects**

## Physical and chemical properties depend on the size!!

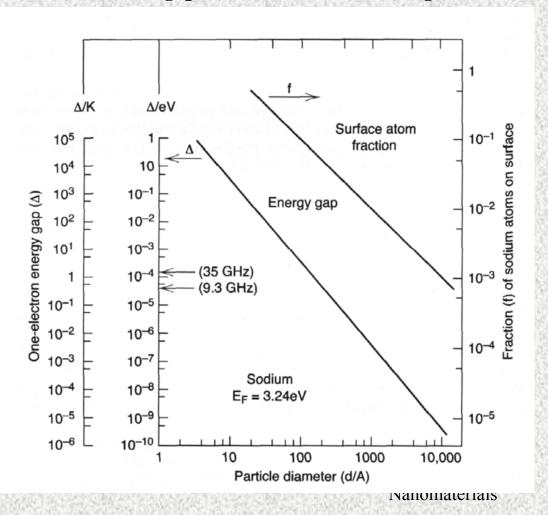

## **Metal-to-Insulator Transition**

#### **Metal-to-Insulator Transition**

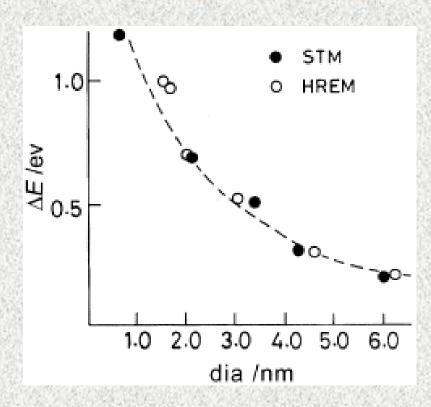

#### Band gap increases with decreasing size

Metallic behavior
Single atom cannot behave
as a metal
nonmetal to metal transition
100-1000 atoms

Magnetic behavior Single domain particles large coercive field

#### **Metal-to-Insulator Transition**

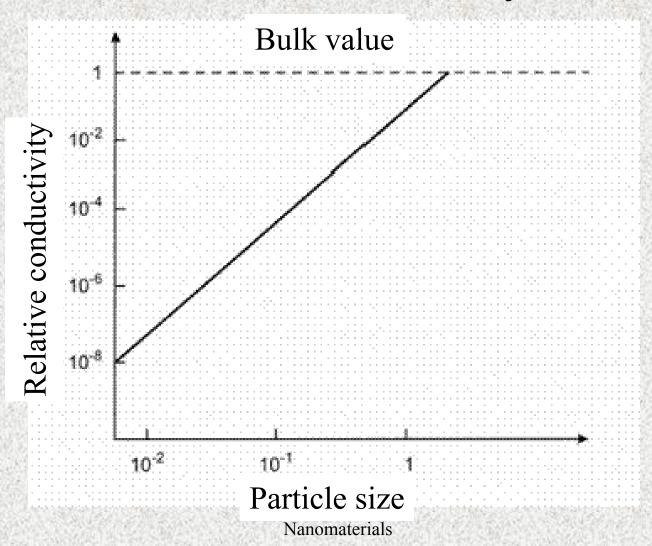

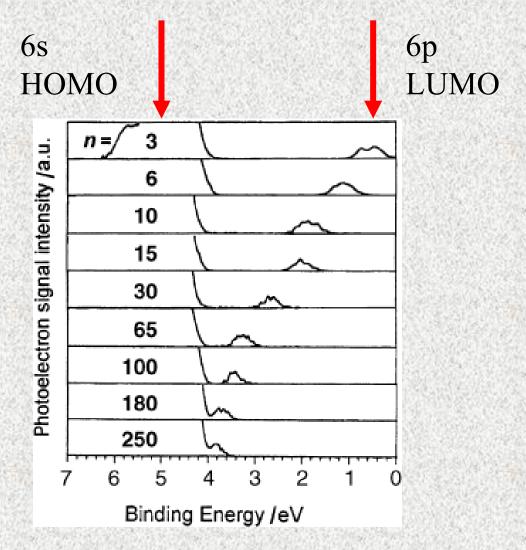

The increase in the core-level binding energy in small particles poor screening of the core charge

the size-induced metal-nonmetal transition in nanocrystals

Variation of the shift,  $\Delta E$ , in the core-level binding energy (relative to the bulk metal value) of Pd with the nanoparticle diameter

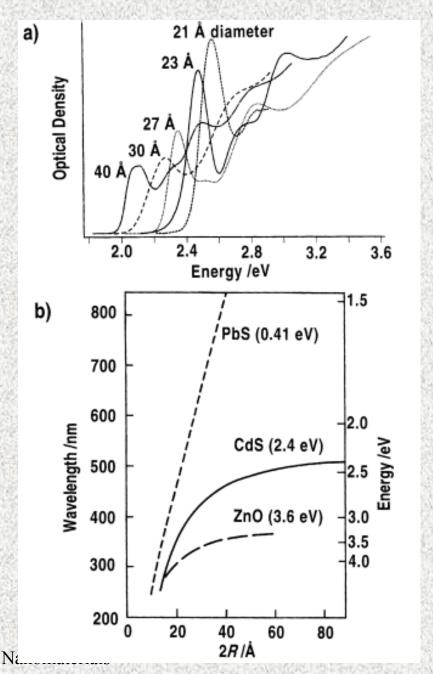

# **Electrical Conductivity**

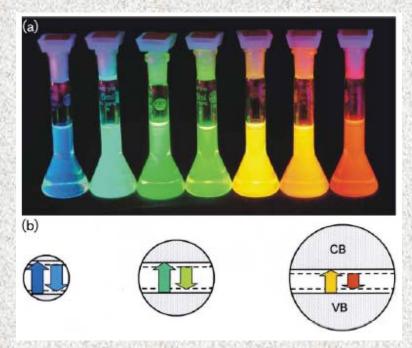

Photoelectron spectra of Hg clusters of nuclearity n The 6p peak moves gradually towards the Fermi level the band gap shrinks with increase in cluster size

- a) Absorption spectra of CdSe nanocrystals (at 10 K) of various diameters
- b) Wavelength of the absorption threshold and band gap as a function of the particle diameter for various semiconductors. The energy gap in the bulk state in parenthesis

## **Quantum Confinement Effects**

Fluorescence of CdSe-CdS core-shell nanoparticles with a diameter of 1.7 nm (blue) up to 6 nm (red)

Smaller particles have a wider band gap

### **Bohr Radii**

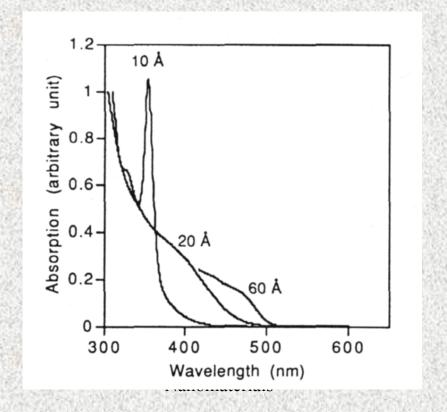

quantum confinement -particles must be smaller than the Bohr radius of the electron-hole pair

semiconductor	$r_{ m B}$ (Å)	$E_{\mathrm{g}} \ (\mathrm{eV})$

## **Nanoengine**

Nanomotor funguje díky katalýze (viz obr.) U platinové části tyčinky se štěpí peroxid vodíku  $(H_2O_2)$  na kyslík  $(O_2)$  a protony (H+). Přebytečné elektrony se přesunují k stříbrozlaté části tyčinky, čímž nastartují redukční reakci  $H_2O_2$  a protonů a vzniká voda. Uvolnění kyslíku a vody vytváří slabé proudění, které žene nanotyčinku kapalinou, a to platinovou částí napřed. Slovo Fliessrichtung na obrázku znamená směr proudění.

Slitina zlata a stříbra se postará o to, že se k ní elektrony přesunují rychleji. Tím se urychlí i rozpad pohonné látky a tyčinky jsou o to rychlejší.

150 mikrometrů za sekundu
