Nature 363, 443 - 445 (03 June 1993); doi:10.1038/363443a0

A new species of living bovid from Vietnam

VU VANHUNG, PHAM BONG QUAO, HOANGNGOC CHINH DOTOUC, PETER ARCTANDER & JOHN MACKENZIE

Forest Inventory and Planning Institute, Ministry of Forestry, Hanoi, Vietnam

Asian Bureau for Conservation, 18/E Capital Building, 175-191 Lockhart Road, Wan Chai, Hong Kong

To whom correspondence should be addressed.

IN May 1992 a joint survey by the Ministry of Forestry and World Wide Fund for Nature of the Vu Quang Nature Reserve, Ha tinh province, found three sets of long straight horns of a new bovid (*Mammalia, Artiodactyla*) in hunters' houses¹. None of the specimens had dentition. On four follow-up visits by Vietnamese scientists new specimens were discovered and surveys of forests in neighbouring Nghe an province revealed more localities and some partial specimens. In all, we have examined more than 20 specimens. Three have complete upper skulls and dentitions, two have lower jaws and dentitions. Three complete skins have been collected. The specimens are distinct in appearance, morphology and DNA sequence and cannot be ascribed to any known genus. Only two bovid genera are known from this part of Asia, *Bos* and *Naemorhedus* = *Capricornis*^{2,3}. A new genus and species are therefore

Pseudonovibos spiralis - ling 1994

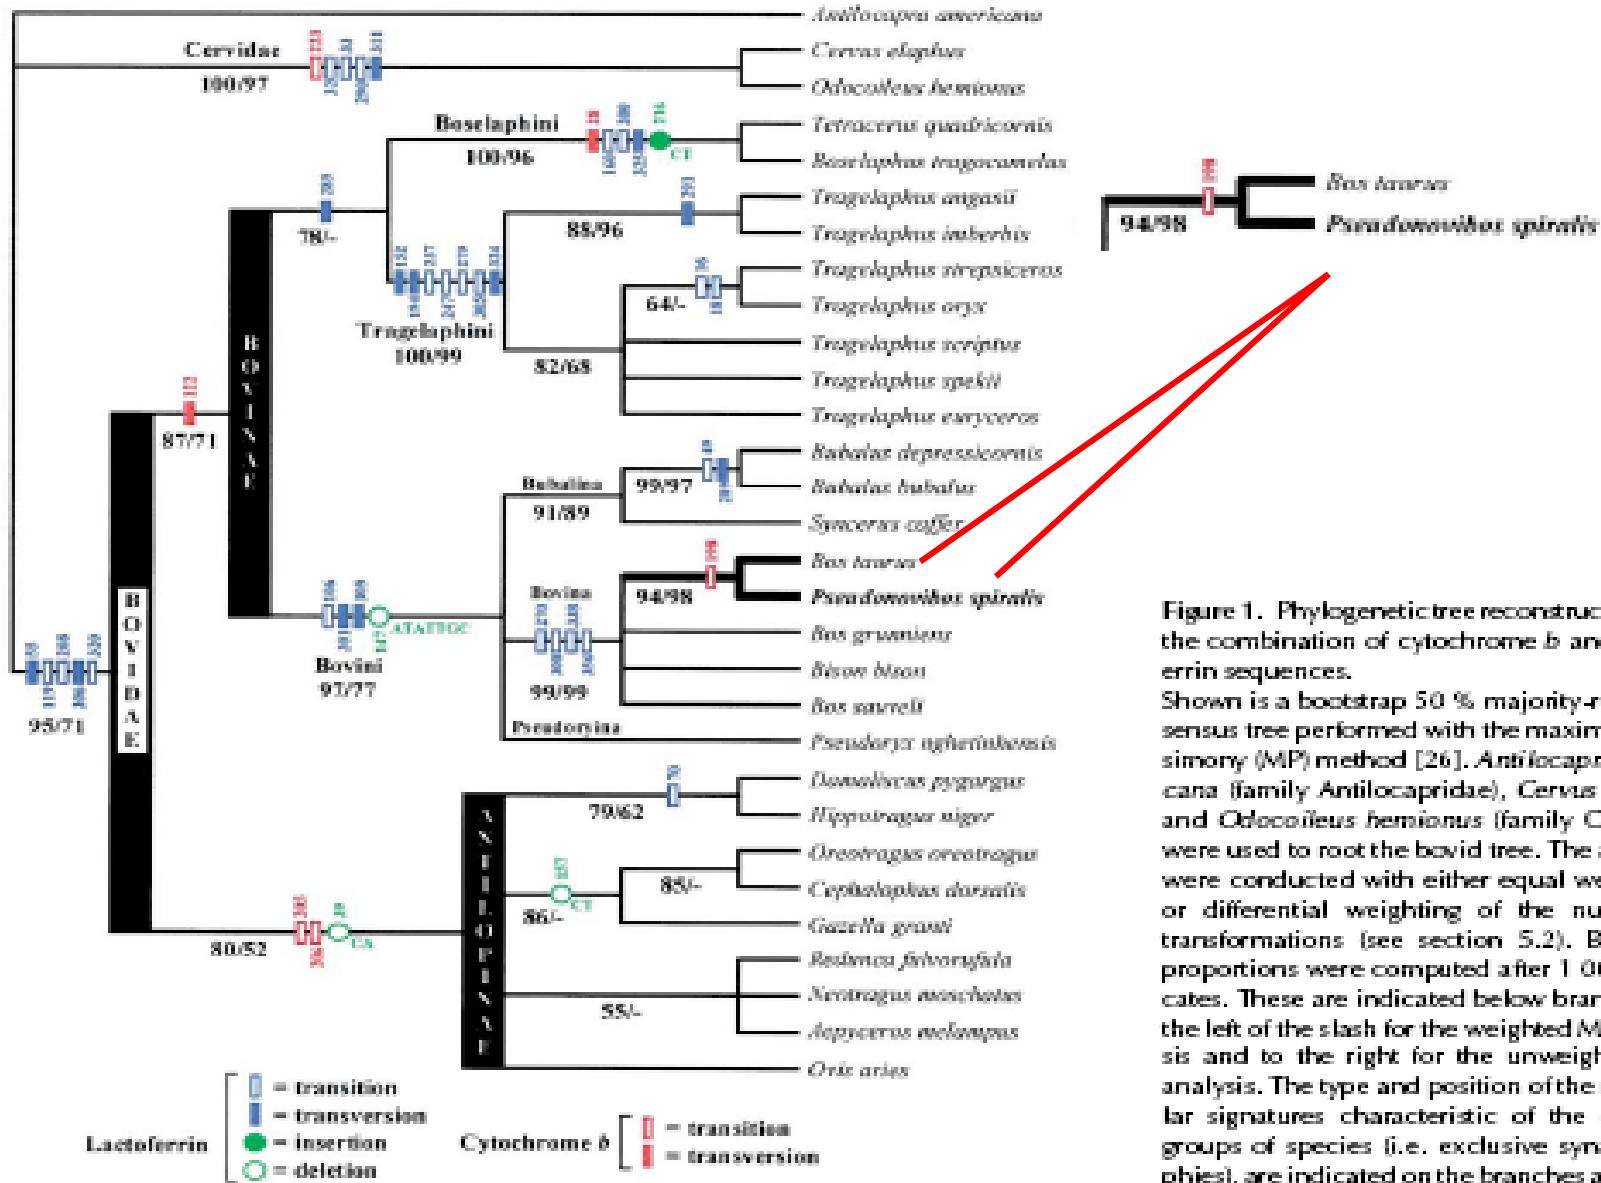

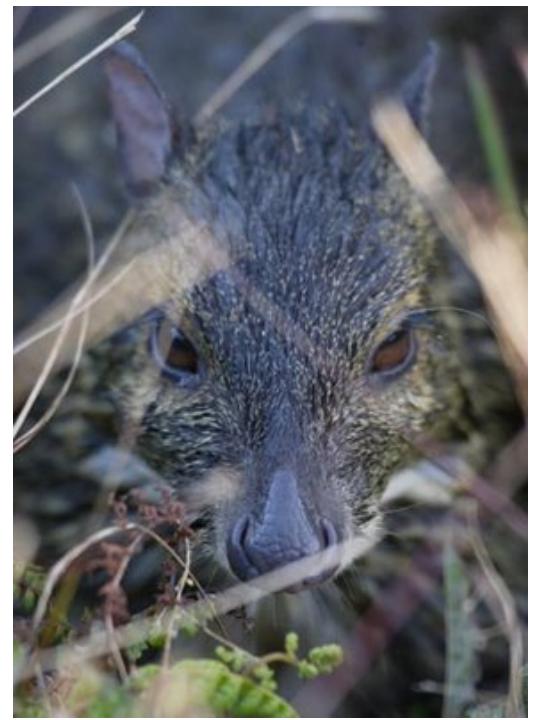

Figure 1. Phylogenetic tree reconstructed from the combination of cytochrome b and lactoferrin sequences. Shown is a bootstrap 50 % majority-rule consensus tree performed with the maximum parsimony (MP) method [26]. *Antilocapra americana* (family Antilocapridae), *Cervus elaphus* and *Odocoileus hemionus* (family Cervidae) were used to root the bovid tree. The analyses were conducted with either equal weighting, or differential weighting of the nucleotide transformations (see section 5.2). Bootstrap proportions were computed after 1 000 replicates. These are indicated below branches, to the left of the slash for the weighted MP analysis and to the right for the unweighted MP analysis. The type and position of the molecular signatures characteristic of the different groups of species (i.e. exclusive synapomorphies), are indicated on the branches as shown in the key.

A NEW SPECIES OF LIVING BROCKET DEER
(MAMMALIA: CERVIDAE) FROM THE BRAZILIAN AMAZON

Marc G. M. VAN ROOSMALEN & Pim VAN HOOFT

(LEFT) *Mazama ochroleuca* sp. nov. redrawn from plate depicting *Mazama (gouazoupira) nemorivaga* (Eisenberg, 1989).

(ABOVE) Two spikes of *Mazama americana* above, one of *Mazama ochroleuca* sp. nov. below.

Here we report on the existence of a new species of even-toed ungulate in the Brazilian Amazon, which we name *Mazama ochroleuca* sp. nov., the fair brocket deer. It is intermediate in size between the two known species of brocket deer, *Mazama americana* and *Mazama (gouazoupira) nemorivaga*, and occurs in sympatry with both. Preliminary mitochondrial partial cytochrome b sequences of fair brocket deer compared with that of the sympatric and morphologically most related grey brocket deer {*Mazama (gouazoupira) nemorivaga*} revealed a sequence difference of 3.7%. Divergence time is therefore estimated at 1.0 million years before present. As in other brocket deer, fair brocket deer seem to live solitary or in pairs. In view of recent developments in the Rio Aripuanã basin where it lives and due to its limited distribution, we consider the fair brocket deer highly endangered.

KEY WORDS

New species, Artiodactyla, Cervidae, *Mazama ochroleuca* sp. nov., fair brocket deer, Brazilian Amazon

Mazama ochroleuca 2008

A NEW SPECIES OF LIVING LOWLAND TAPIR (MAMMALIA: TAPIRIDAE) FROM THE BRAZILIAN AMAZON

Marc G.M. van Roosmalen / AAPN Manaus-Amazonas, Brazil

(LEFT) Adapted rendering of a black dwarf lowland tapir.
(ABOVE) On the left a skull of Brazilian lowland tapir, on the right the skull of black dwarf lowland tapir.

Here we report on the existence of a new species of odd-toed ungulate in the Brazilian Amazon, which we name *Tapirus pygmaeus* sp. nov., the black dwarf lowland tapir. It is much smaller than the since long known Brazilian lowland tapir, *Tapirus terrestris*. As in other tapirs, dwarf tapirs seem to live solitary or in pairs. In view of recent developments in the interfluvius where it lives and due to its limited distribution and apparent rariness, we consider the dwarf tapir highly endangered.

KEY WORDS

New species, Perissodactyla, Tapiridae, *Tapirus pygmaeus* sp. nov., black dwarf lowland tapir, Brazilian Amazon

mangabej kipundži - kočkodanovití (*Cercopithecidae*)

because of the terrain, thick secondary forest, and the animal's cryptic nature, sightings were infrequent and poor. It was not until December 2003, during work in the contiguous Livingstone Forest, that the monkey was clearly observed and recognized as a new species of mangabey.

Ndundulu population. The Udzungwa Mountains (Udzungwas: 10,000 km², 07°40'S to 08°40'S and 35°10'E to 36°50'E) lie 350 km to the northeast of Rungwe-Livingstone (4, 5). Supporting circa (ca.) 1017 km² of fragmented forest (6), the Udzungwas receive a maximum annual rainfall of roughly 2200 mm and were previously thought to hold 10 primate species (7), including the endemic Sanje mangabey, *Cercopithecus sanjei*, discovered in 1979 (8).

Two populations of the Sanje mangabey are known from the Udzungwas (7, 9). During visits from 1991 to 2000, ornithologists working in the Ndundulu Forest Reserve (Fig. 1) reported a third population of the Sanje mangabey (10). Subsequent surveys failed to confirm the presence of this species in Ndundulu (7, 9, 11) and led to our intensified surveys in July and September 2004. During these surveys, Sanje mangabeys were not encountered or heard. However, on 7 July 2004, the new species of mangabey was discovered. It now seems certain that the ornithologists had misidentified the new species of mangabey as the Sanje mangabey.

The researchers working on each of these two new populations of mangabeys did not become aware that a second population was known until October 2004.

Lophocebus kipunji Ehardt, Butynski, Jones, and Davenport sp. nov.

Holotype. Adult male in photograph (Fig. 2). Photograph taken in the type locality at 9°07'S 33°44'E (12). The number of individuals in each of the two populations of this species is undoubtedly very small; no

Fig. 2. Holotype: adult male highland mangabey *Lophocebus kipunji* in the type locality, Rungwe-Livingstone, Tanzania. [Photograph by T.R.B. Davenport]

live individual should be collected at this time to serve as the holotype. The Rungwe-Livingstone population is designated the source population for physical specimens in support of the holotype.

Paratype. Adult in photograph (Fig. 3). Sex not known. Photograph taken in Ndundulu Forest Reserve (07°48'45"S 36°31'05"E), Udzungwa Mountains, Tanzania.

Type locality. Rungwe-Livingstone (09°07'S to 09°11'S and 33°40'E to 33°55'E), Southern Highlands, Tanzania.

Diagnosis. Pelage of dorsum light to medium brown, center of ventrum and distal half of

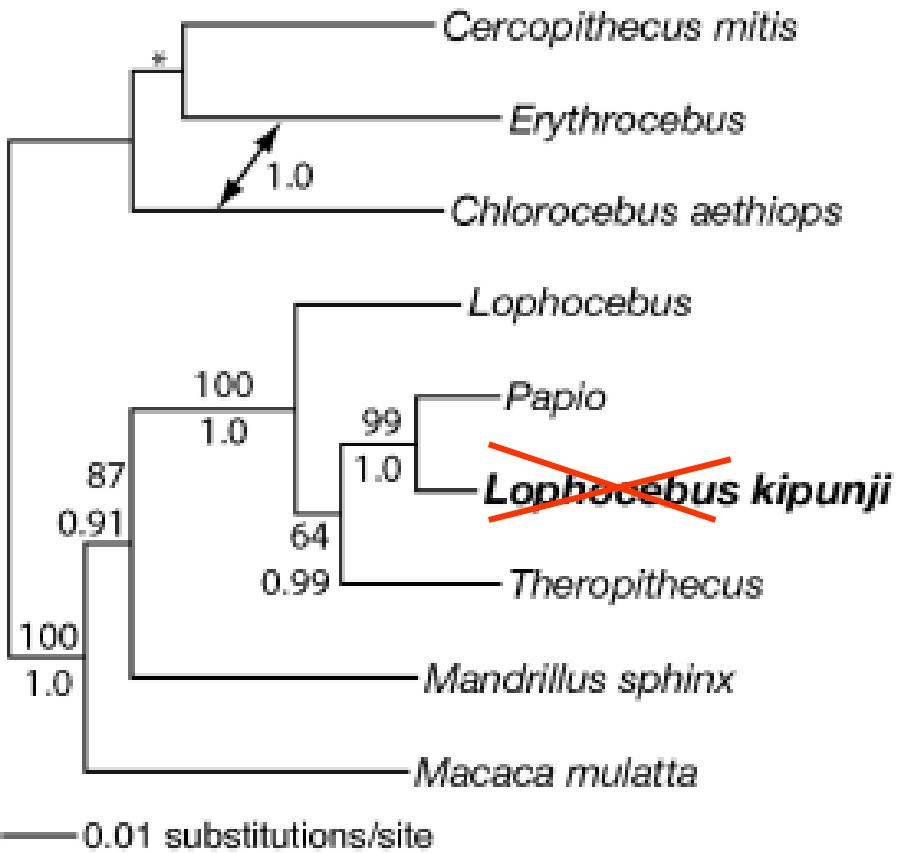

Fig. 3. Paratype: adult highland mangabey *Lophocebus kipunji*, Ndundulu Forest Reserve, Tanzania. [Photograph by T. Jones]

tail off-white. Crown with very long, broad, erect crest of hair. Eyelids black, not contrasting with color of face. Adults emit a distinctive, loud, low-pitched "honk-bark" (Fig. 4). Arboreal. Found only at high altitudes (1300 m up to 2450 m asl) and low-temperature tolerant; temperatures in Rungwe-Livingstone drop to at least -3°C.

Description. A primarily brown, medium-sized, long-tailed, arboreal monkey. Muzzle elongated. Facial skin, including eyelids, black. Suborbital fossae "tear line" pronounced. Eyes brown. Pelage light to rufous brown except as follows: center of ventrum and distal half of tail, white to off-white; hands and feet, black; lower forelimbs, dark brown to black. Cheek whiskers long. Crown with very long, broad, stiff, upright crest of hair. Shoulder cape present in some individuals, although there is variation in length and color. White of ventrum sharply offset from brown in at least

Diverzita savců v Evropě

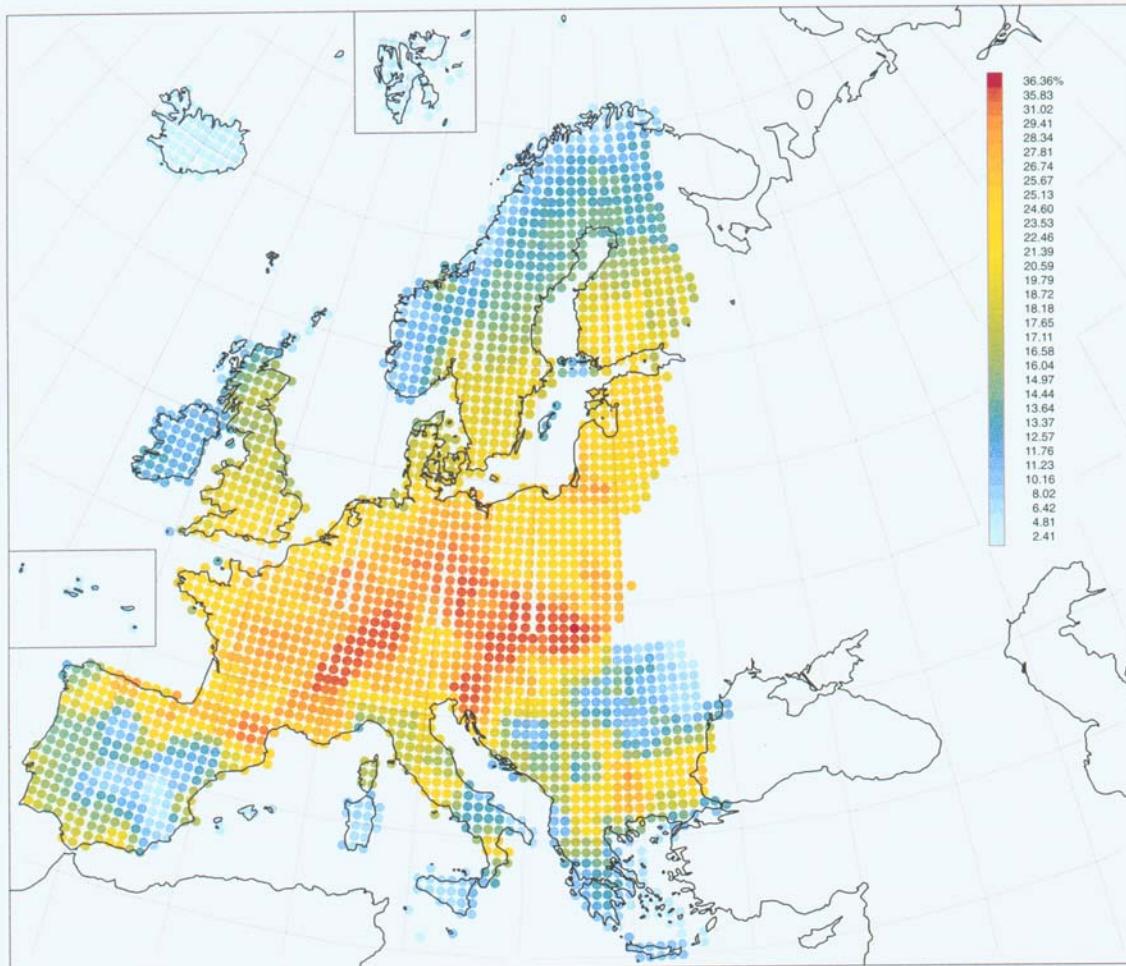

Figure 1 Species richness of mammals across Europe. This illustrative map was prepared using Worldmap software and shows species richness (number of species per grid square) with one level of smoothing. The entire atlas dataset has been used, including introduced species. There are some differences between the *Atlas Flora Europaea* UTM grid used by this software and the one used in the Atlas, particularly around the south-eastern borders of Europe and also in the treatment of some island groups.
