

Gerhard Lammel: “Trends and Advances in Atmospheric and Environmental Chemistry”

**Cloud chemistry: Ozone, acidity formation, dimethyl sulphide
Atmospheric aerosol, its composition, surface and bulk particle reactions**

Cloudwater - introduction, significance

- 15% of the volume of the troposphere filled with clouds
- liquid water content $L = 0.1\text{-}2 \cdot 10^{-6} V_{\text{water}}/V_{\text{air}} = 0.1\text{-}2 \text{ g/m}^3$
 $= (0.1\text{-}2) \cdot 10^{-3} \text{ L/m}^3 < 10\%$ of total water content ($10\text{-}40 \text{ g/m}^3!$)
- only $\approx 10\%$ of clouds will rain out, while 90% will recycle aerosol particles
- lifetime of clouds hours-days, of cloud droplets ($D=5\text{-}50 \mu\text{m}$) minutes
- aqueous composition: dissolved ($c_i \approx 10^{-6} \text{-} 10^{-3} \text{ M}$) + eventually non-dissolved constituents, droplet-size dependent, $c_i(D)$
- humidity/supersaturation S ($:=\text{rh}-1$) is altitude (above cloud base)-dependent

Terminology:

- Hydrometeors = cloud droplets + ice particles + rain droplets + snow flakes + graupel + ...
- Wet deposition = rain + snow fall + rime
- Wash-out = below-cloud scavenging + in-cloud scavenging of both gases and particles
- in-cloud scavenging of gases = dissolution
- Occult deposition = droplet deposition from clouds, fogs else than rain or snow fall

some units:

- $1 \text{ M} = 1 \text{ mol/L}$
- $\text{pH } 7 \leftrightarrow c_{\text{H}_3\text{O}^+} = 10^{-7} \text{ M}$

Henry coefficients

**Solubility increases with decreasing temperatures,
e.g. 78, 63 and 53% of O₂ at 0°C is soluble at 10, 20 and 30°C, respectively.**

Table 3 Henry's law partition coefficients K_H^\ominus at $T = 298$ K, heats of vaporization ΔH_{soln} divided by the gas constant R_g , mass accommodation coefficients α , transfer coefficients k_t , and the associated time constants for the approach to Henry's law equilibrium

Sulfuric acid formation in the aqueous phase

Dissolution of gases - thermodynamic equilibrium

...with diluted solutions (ideal behaviour).

The in-cloud scavenged fraction of gaseous molecules is dependent on water solubility:

$$\begin{aligned}\varepsilon_{i(g)} &= n_{i(aqu)} / (n_{i(aqu)} + n_{(g)}) = n_{i(aqu)} / [n_{i(aqu)} + p_i V_{air} / (R_g T)] = \\ &= n_{i(aqu)} / [n_{i(aqu)} + H_i n_{i(aqu)} V_{air} / (R_g T n_{H_2O})] = \\ &= [1 + H_i M_w / (R_g T L)]^{-1}\end{aligned}$$

with: Henry coefficient H_i [at] = $p_i n_{i(aqu)} / n_{H_2O} = p_i x_i = p_i / (c_i / 10^3 / M_w)$,
liquid water content L [g/m³]
gas constant $R_g = 8.206 \times 10^{-5}$ m³ at/mol/K, M_w [g/mol], 10^3 [cm³/L]

(Warneck, 1986)

Another, more common Henry coefficient:

$$K_H [\text{M at}^{-1}] = 10^2 s / M_w p = (10^3 / M_w) \times \rho_{H_2O} / H$$

$$\text{solubility } s(T) [\text{mg/L}] = s(T_0) \times \exp[-\Delta H_{\text{sol}} / R_g \times (1/T - 1/T_0)]$$

... confusing: there are more common so-called ,Henry coefficients :

Air-water partitioning coefficient K_{aw} [] = $M_w p / (10^5 R_g T s) = 1 / (10^3 R_g T K_H)$

Henry coefficient H' [Pa m³/mol] = $R_g T K_{aw} = 10^{-2} / K^H [M/at]$

Tropospheric ozone and clouds

Ozone reactions

Ozone is a source of radicals and H₂O₂ in cloudwater:

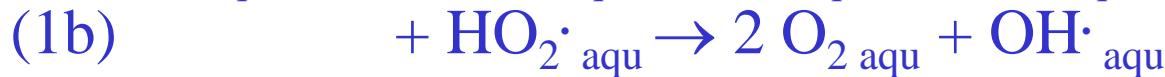

TABLE 1 Gas-phase, gas-liquid equilibrium and aqueous-phase reactions

Gas-phase reactions		Rate constant*	Ref.

G, E and A are gas-phase reactions, gas-liquid equilibrium and aqueous-phase reactions, respectively. These are the most important reactions from the more extended reaction scheme in the model. Some reactions summarize several reaction steps. Aqueous-phase processes at mid-latitudes in the Northern Hemisphere are simulated at pH 4.5, for other latitudes in Table 2 pH 5 is adopted⁵⁰. Photolysis rate coefficients and water vapour concentrations in clouds are kept equal to those during clear sky to emphasize photochemical differences. Daytime average photolysis rates are applied. Accommodation coefficients, as used for gas-to-aqueous-phase transfer processes⁵¹, are taken from refs 51–56. For those components with unknown accommodation coefficients we assume a value of 0.05.

* Reaction rate constants of first-order reactions are in s^{-1} , of second-order reactions in the gas phase (G) in $\text{molecule}^{-1} \text{cm}^3 \text{s}^{-1}$, in the aqueous phase (A) in $\text{mol}^{-1} \text{l s}^{-1}$. Photodissociation rate constants are calculated per second, latitude and altitude. The given values pertain to the Equator in July, at 700 mbars.

$\ddagger K_{298}$ is in $\text{mol}^{-1} \text{atm}^{-3}$ for Henry's law constants and in mol l^{-3} for aqueous-phase equilibria. The temperature dependence is calculated by $K = K_{298} \exp [(-\Delta H/R)(1/T) - (1/298)]$.

\ddagger Assumed.

$\ast E_a$ values are taken from ref. 4.

\ddagger J.L., thesis in preparation.

\ddagger Gas-to-aqueous-phase transfer of N_2O_5 is limited by gas-phase diffusion and transfer through the interface. We assume that reaction A10 then occurs instantaneously, so that dissolution is irreversible.

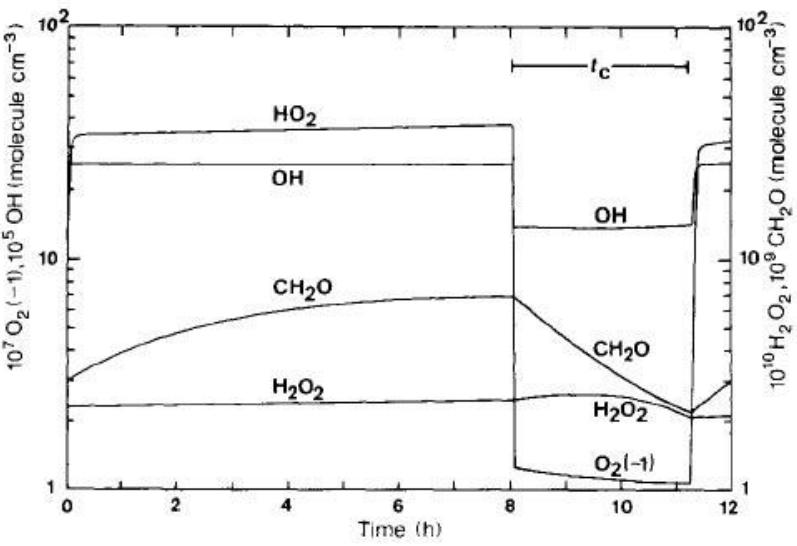

FIG. 2 Concentrations of some gases during sunlit hours of day 14 of the simulations, pertaining to the Equator at 3 km altitude (case 6, Table 2 and 3a), with NO_x fixed. For the cloudy period (t_c) total gas-phase plus aqueous-phase concentrations are depicted. $O_2(-1) = HO_2(\text{gas}) + HO_2(\text{aq}) + O_2^-$.

Differences in solubility and chemical reactivity in the aqueous phase result in changed (overall) chemistry of the atmosphere. pH dependencies, e.g. O_3 sink A6
 $(O_3 + O_2^- + H_2O \rightarrow)$
 O_3 , OH , NO_x overestimated when clouds are neglected

(Lelieveld & Crutzen, 1990)

Solubility of $\text{CO}_2(\text{g}) \rightleftharpoons \text{CO}_2(\text{aq}) + 20 \text{ kJ/mol}$

$$(1) \quad K_H = c_{\text{CO}_2 \text{ aqu}} / p_{\text{CO}_2} = 3.4 \times 10^{-7} \text{ mol/L/Pa (298 K)}$$

$$(2) \quad K_{A1} = (c_{\text{HCO}_3^-} c_{\text{H}_3\text{O}^+}) / c_{\text{CO}_2 \text{ aqu}} = 10^{-6.35}$$

$$(3) \quad K_{A2} = (c_{\text{CO}_3^{2-}} c_{\text{H}_3\text{O}^+}) / c_{\text{HCO}_3^-} = 10^{-10.33}$$

Dissolved fraction is pH dependent, expressed as the effective Henry coeff. H^* :

$$K_{H \text{ CO}_2}^* = (c_{\text{CO}_2 \text{ aqu}} + c_{\text{HCO}_3^-} + c_{\text{CO}_3^{2-}}) / p \text{ (mol/L/Pa)}$$

$$K_H^* = K_H (1 + K_{A1} / c_{\text{H}_3\text{O}^+} + K_{A1} K_{A2} / c_{\text{H}_3\text{O}^+}^2)$$

pH of water in the atmosphere in equilibrium with CO_2 ($p_{\text{CO}_2} = 36 \text{ Pa}$):

$$(1) \text{ in (2): } c_{\text{HCO}_3^-} c_{\text{H}_3\text{O}^+} = K_{A1} K_H p_{\text{CO}_2}$$

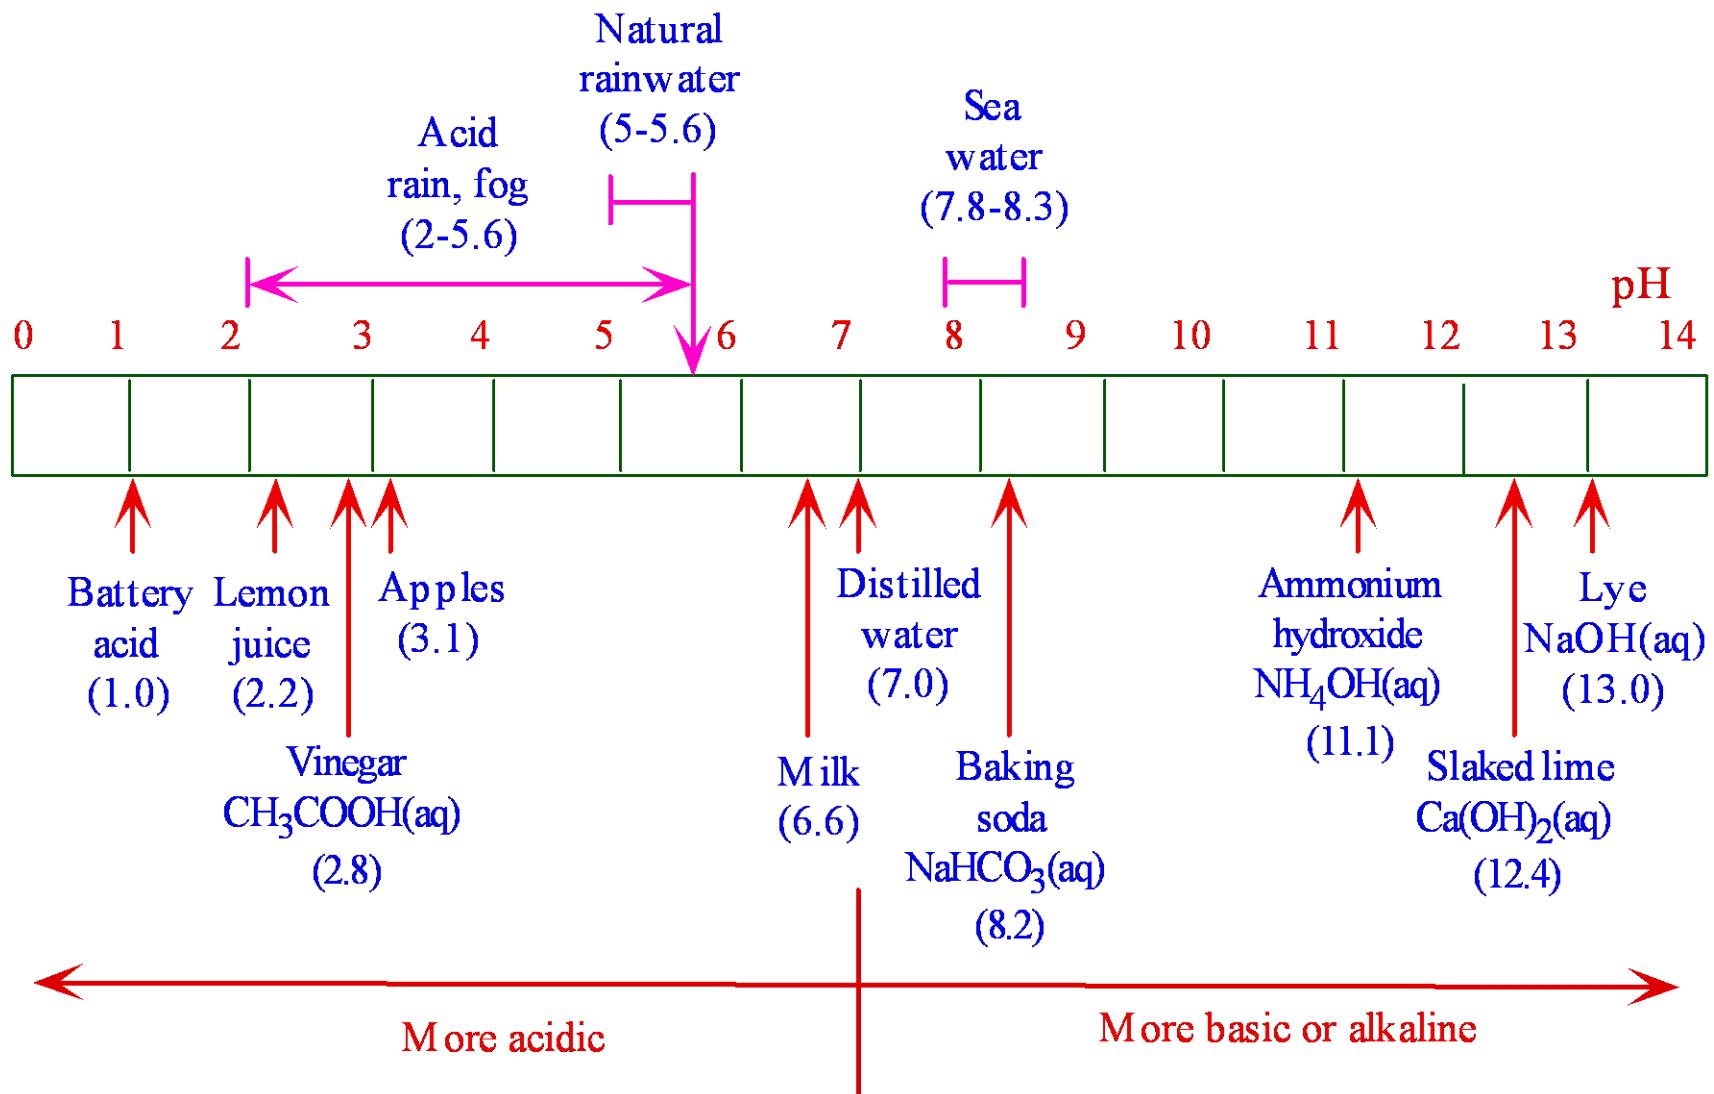

$$c_{\text{HCO}_3^-} = c_{\text{H}_3\text{O}^+}$$

$$c_{\text{H}_3\text{O}^+} = (K_{A1} K_H p_{\text{CO}_2})^{0.5}$$

$$\text{pH} = -0.5 (-pK_{A1} - \log K_H - \log p_{\text{CO}_2})$$

$$\text{pH} = 0.5 (6.35 - \log 3.4 \times 10^{-7} - \log 36) = 5.63$$

pH scale

(Graedel & Weschler, 1981; Warneck, 1999)

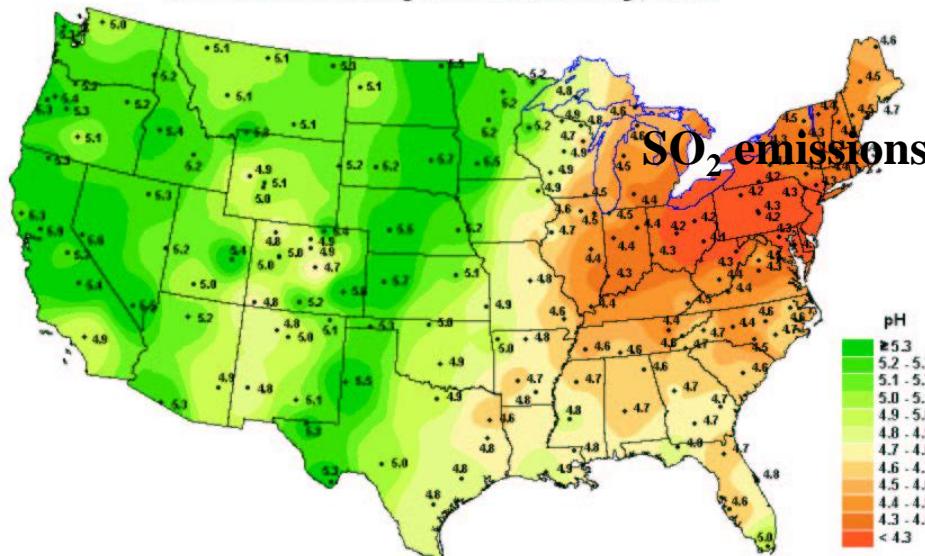

Acidity formation in the troposphere: sulfuric acid

Oxidations are pH dependent, because in individual steps of the reactions of SO_2^{aq} , $\text{HSO}_3^-_{\text{aq}}$ and $\text{SO}_3^{2-}_{\text{aq}}$ (which are present in pH-dependent fractions according to K_{S1} , K_{S2}) is H^+_{aq} consumed or formed.

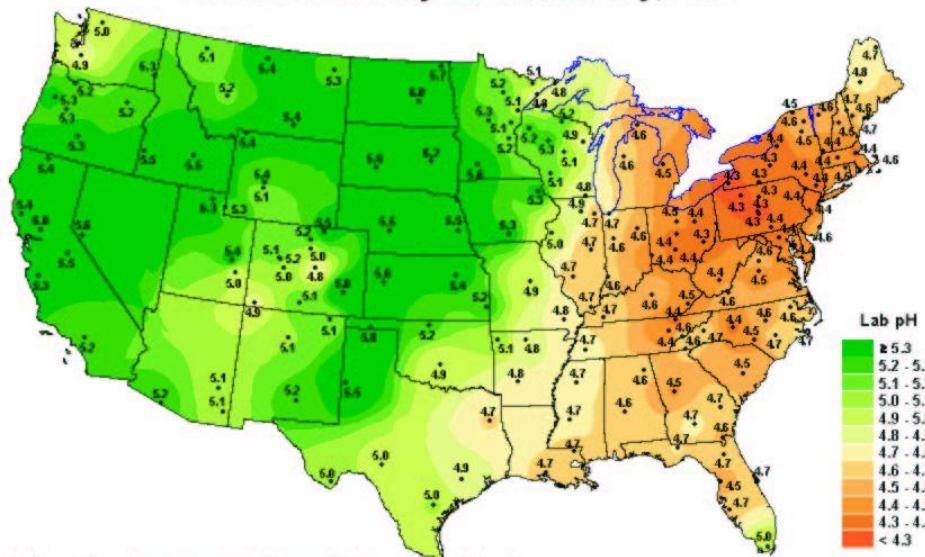

for L = $V_{\text{H}_2\text{O(l)}}/V = 3 \times 10^{-6}$ (Seinfeld, Calvert)

- (4b) $\text{CH}_3\text{SCHO} + \text{OH}\cdot \rightarrow \text{CH}_3\cdot + \text{COS} + \text{H}_2\text{O}$

major

minor

Formation of SO_2

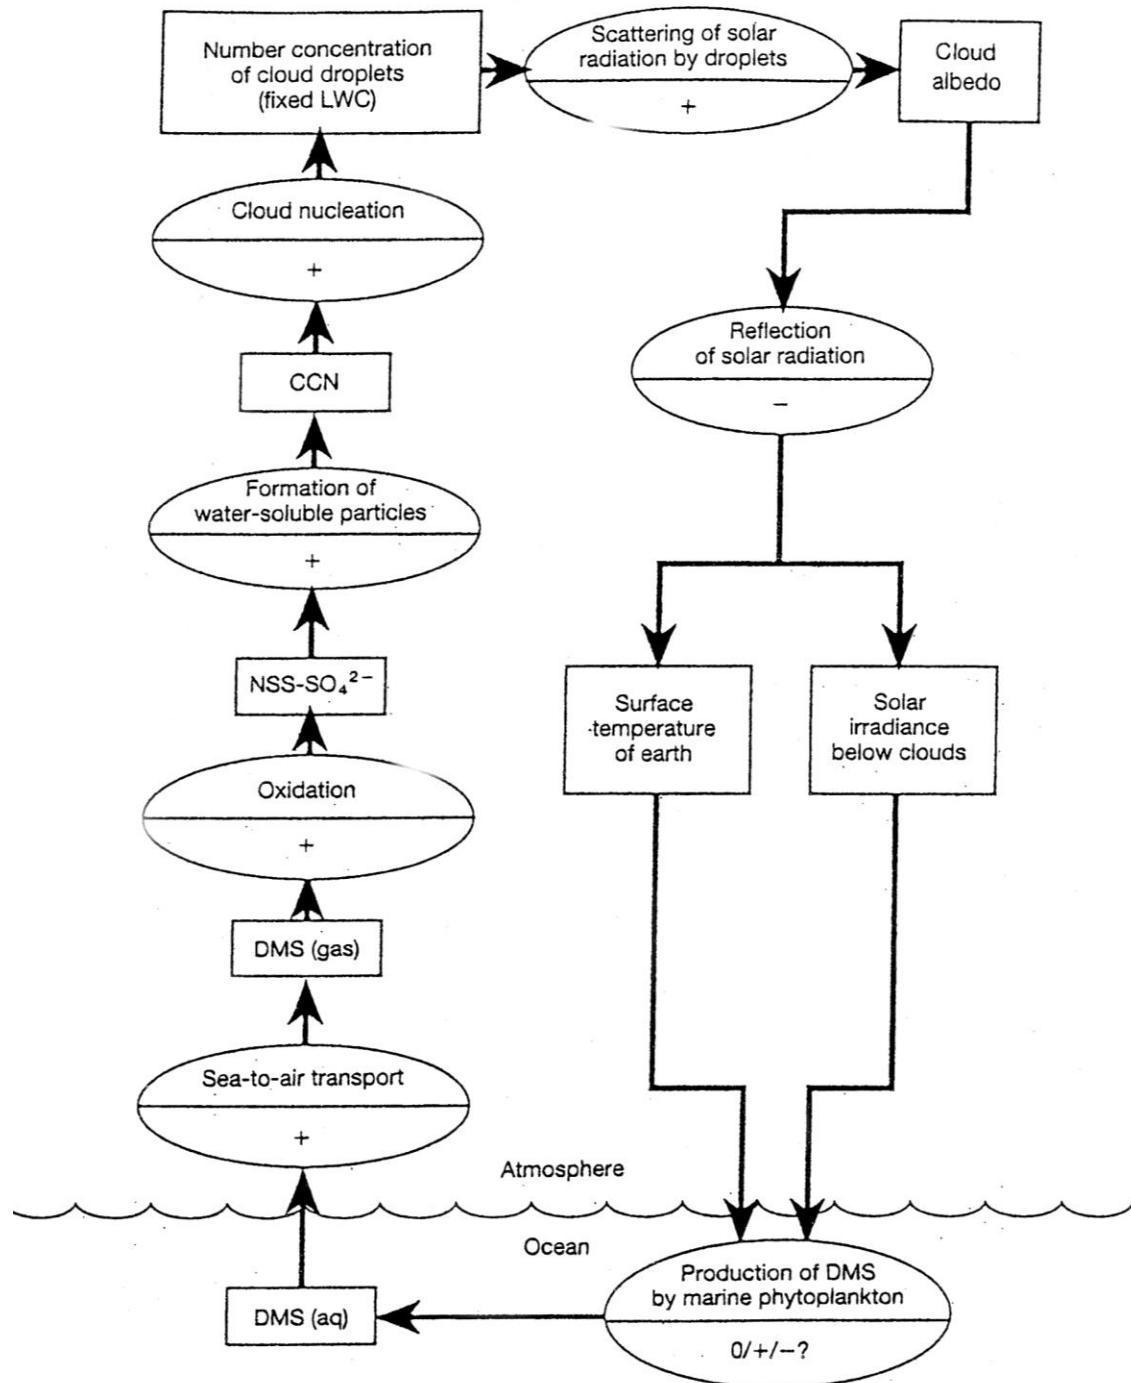

in the marine boundary layer:

Hypothetical negative feedback mechanism in the marine boundary layer:

- CH_3SCH_3 emission
- more clouds
- less radiative flux
- less phytoplankton
- less CH_3SCH_3 emission

(CLAW hypothesis; *Charlson et al., 1987*)

Heterogeneous reactions in the gas/water droplet system

In phase equilibrium

Acidity formation in the troposphere: sulfuric acid

Example: $c_{\text{SO}_2} = 2 \text{ nmol m}^{-3}$, $c_{\text{H}_2\text{O}_2} = 40 \text{ nmol m}^{-3}$, $T = 298 \text{ K}$
(near Bermuda 1988)

1. Gas-phase: $dc_{\text{S(VI)}}/dt = 5.6 \times 10^{-6} \text{ nmol m}^{-3} \text{ s}^{-1}$

2. Aqueous phase ($L = 3 \times 10^{-8}$, pH=7):

$$\begin{aligned} dc_{\text{SO}_4^{2-}}/dt &= k_4 p_{\text{H}_2\text{O}_2} K_{\text{H}_2\text{O}_2} p_{\text{SO}_2} K^*_{\text{HSO}_2} (\text{M s}^{-1}) \\ &= (4 \times 10^7 \times 10^{-7}) \times 40 \times 10^{-9} \times 1 \times 10^5 \times 2 \times 10^{-9} \times 3.4 \times 10^5 \end{aligned}$$

$$\begin{aligned} K^*_{\text{HSO}_2} &= K_{\text{HSO}_2} \times (1 + K_{\text{A1}} / c_{\text{H}^+} + K_{\text{A1}} K_{\text{A2}} / c_{\text{H}^+}^2) = \\ &= 3.4 \times 10^5 \text{ M/atm} \end{aligned}$$

$$\begin{aligned} dc_{\text{S(VI)}}/dt &= dc_{\text{S(VI)}}/dt (\text{M s}^{-1}) \times L (\text{L m}^{-3}) \times 10^9 (\text{nmol mol}^{-1}) = \\ &= 32 \times 10^{-6} \text{ nmol m}^{-3} \text{ s}^{-1} \end{aligned}$$

Critical loads concept to protect ecosystems

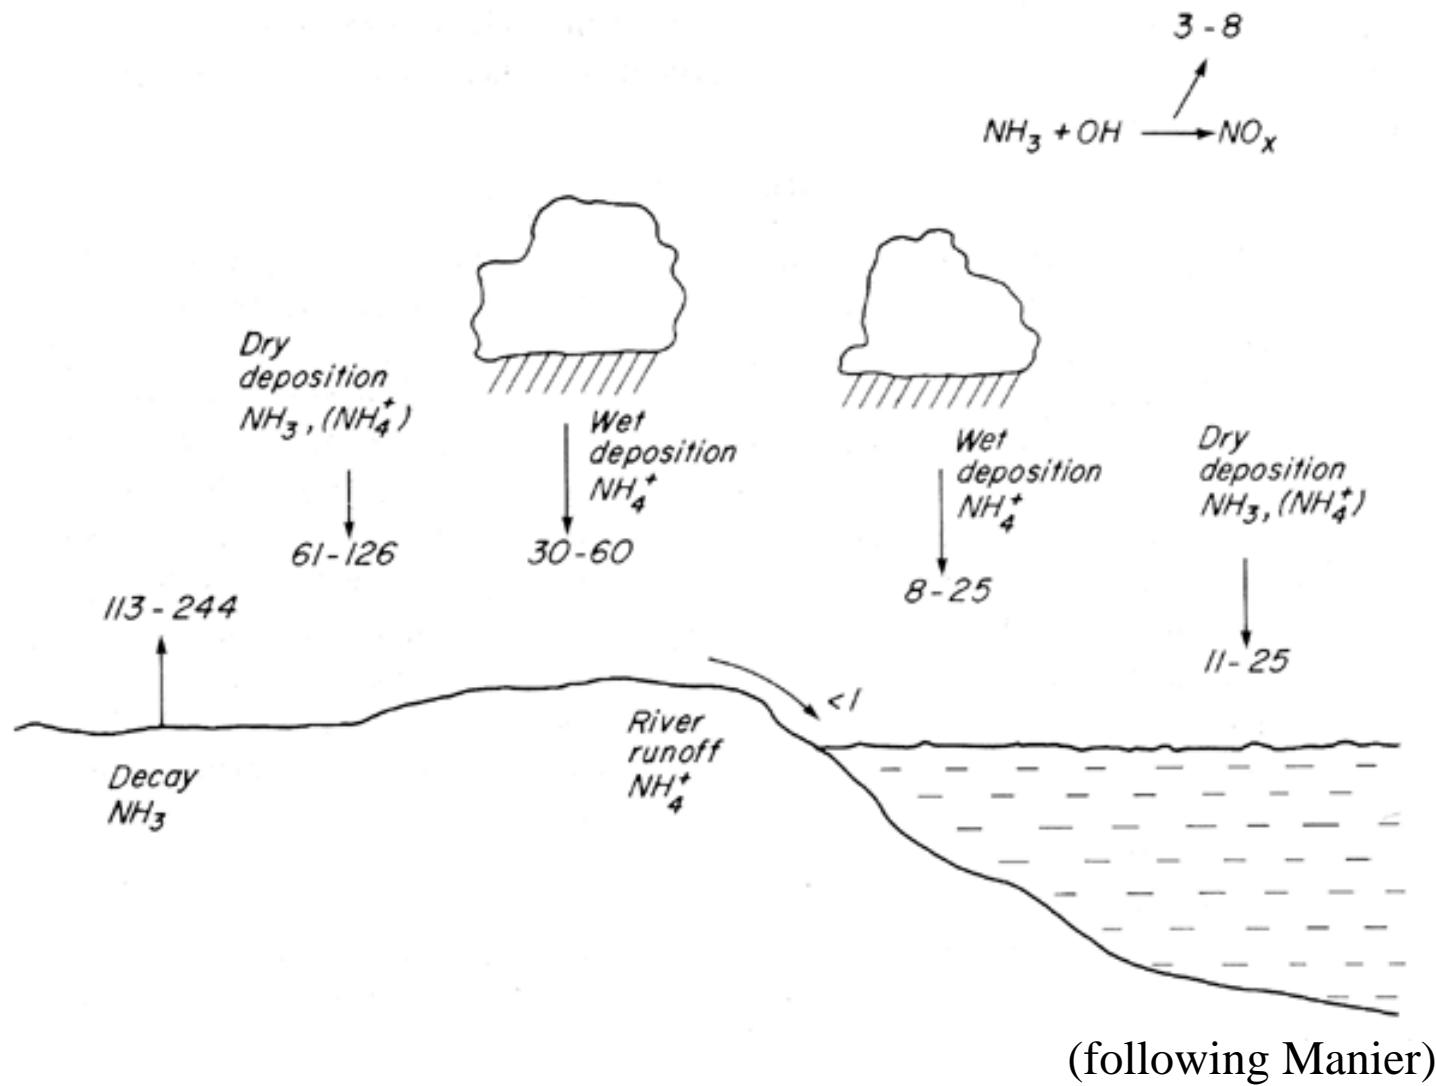

Mapping of critical loads „...below which harmful effects in ecosystem structure and function do not occur according to present knowledge“:

Determines which loads of pollutants and combinations thereof will not cause adverse effects, do not exceed ecosystem resilience (*PNEC*).

- + Protection of vulnerable areas is possible (protection of 95% of the area is common)
- + Accounts for dynamics, mostly however based on steady state-assumption and therefore neglecting the very slow dynamics of the soils
- - Scale problems when matching exposure (deposition model output) and vulnerabilities (mapped ecosystems)
- - normative steps are not transparent
- Integrated Assessment Modelling (IAM) under the auspices of the Convention on Long-range Transboundary Air Pollution (CLRTAP): Study various scenarios of emissions and related abatement costs + depositions and related exceedances of thresholds (*Alcamo et al., 1987*, besides others)

Courtesy of: Cambra-López et al., 2010

Aerosol microphysical processes

Atmospheric residence time $\tau = f(D)$:

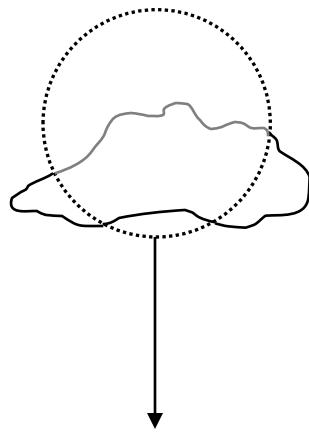

Atmospheric residence time / dry deposition

Diameter (μm)	Time to Fall 1 km	Diameter (μm)	Time to Fall 1 km
0.0005	9630 y	4	23 d
0.02	226 y	5	14.5 d
0.1	36 y	10	3.6 d
0.5	3.2 y	20	23 h
1	326 d	100	1.1 h
2	89 d	1000	4 m
3	41 d	5000	1.8 m

Particle size – not trivial !

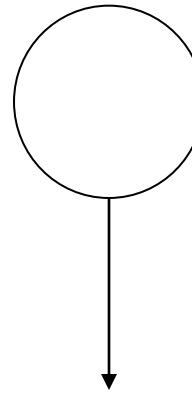

Irregular particle

$$d_e = 5.0 \mu\text{m}$$
$$\rho = 4 \text{ g cm}^{-3}$$
$$\chi = 1.36$$

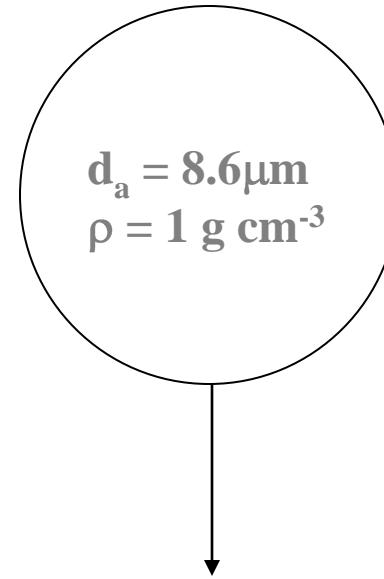

Stokes's equivalent sphere

$$d_s = 4.3 \mu\text{m}$$
$$\rho = 4 \text{ g cm}^{-3}$$

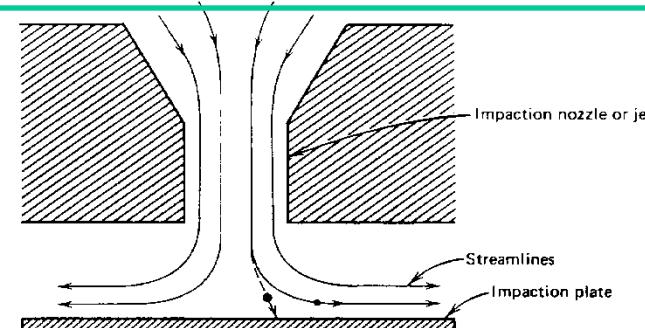

Aerodynamic
equivalent sphere

$$d_a = 8.6 \mu\text{m}$$
$$\rho = 1 \text{ g cm}^{-3}$$

Terminal velocity of all three particles = 0.22 cm s^{-1}

The aerodynamic diameter is the diameter of the unit density sphere that has the same settling velocity as the particle

Nucleation events in polluted air

New Delhi, India, 28.-31.10.2002

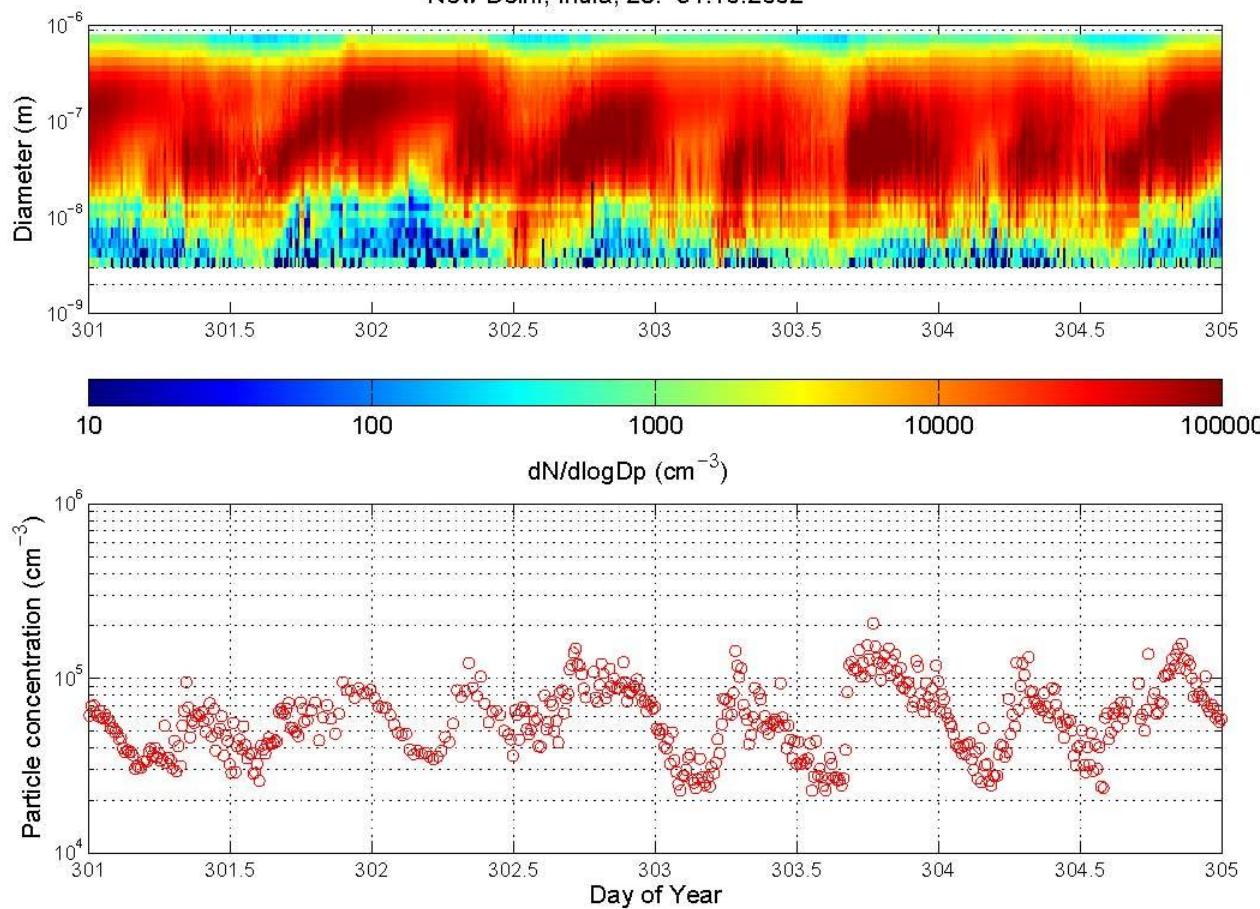

Fig. 2. Measured aerosol number size distribution **(a)** and number concentration **(b)**. The x-axis represents the time and y-axis in (a) particle diameter (m) and in (b) integrated particle concentration (cm⁻³) for the same period. The color in the (a) represents particle concentration (dN/dlogD_p).

Primary particle formation (nucleation)

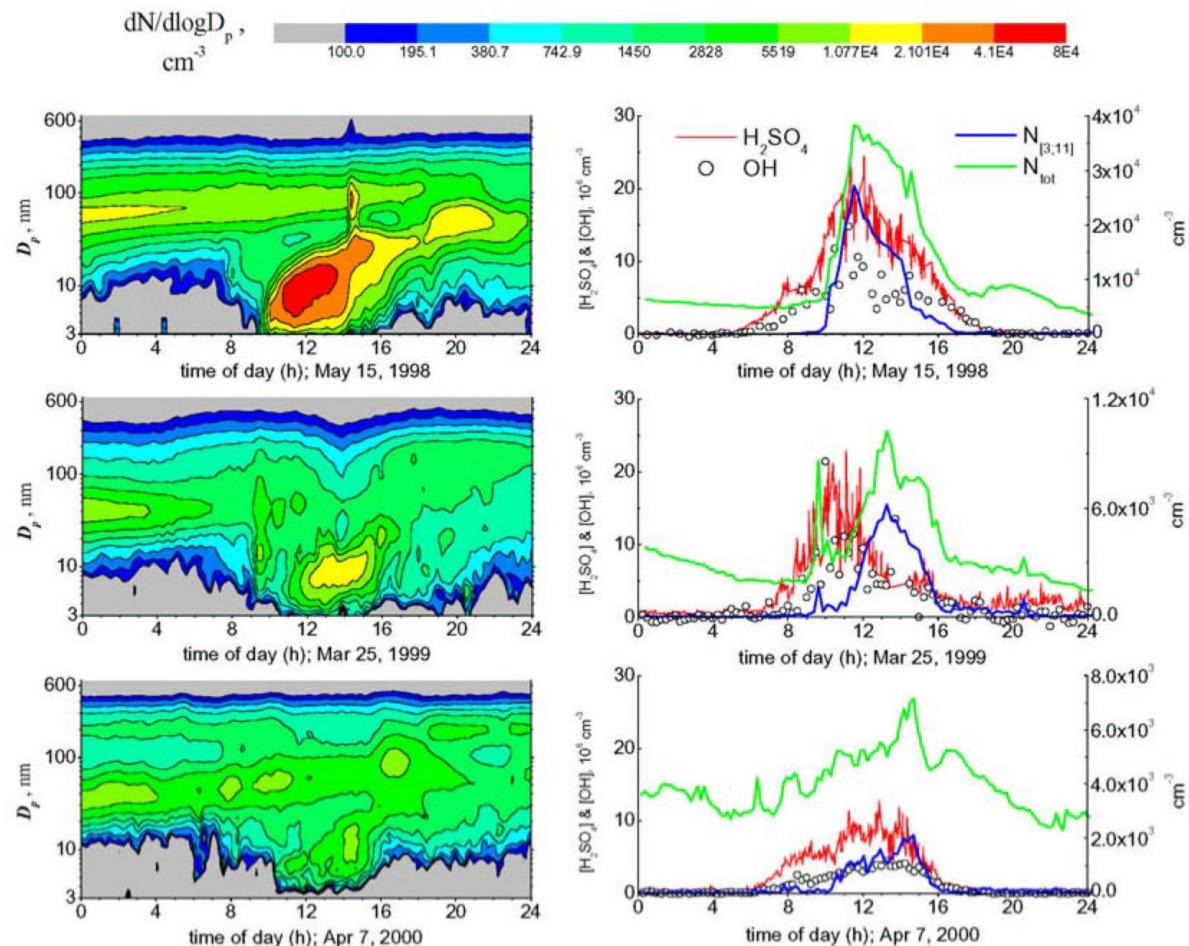

Nucleation events:

Reasons for occurrence of nucleation events unclear. No simple correlations, key factors unknown. Example: 3 different events on Hohenpeissenberg 1998-2000 (*Birmili et al., 2003*).

The nucleation rate is mostly 2nd order in H₂SO₄, in general 1st to 2nd. This suggests the prevalence of a bimolecular reaction (collision) of 2 clusters with each one H₂SO₄ molecule for formation of the critical cluster

(*Weber et al., 2006*).

condensational growth

Aerosol effects

Atmospheric chemistry:

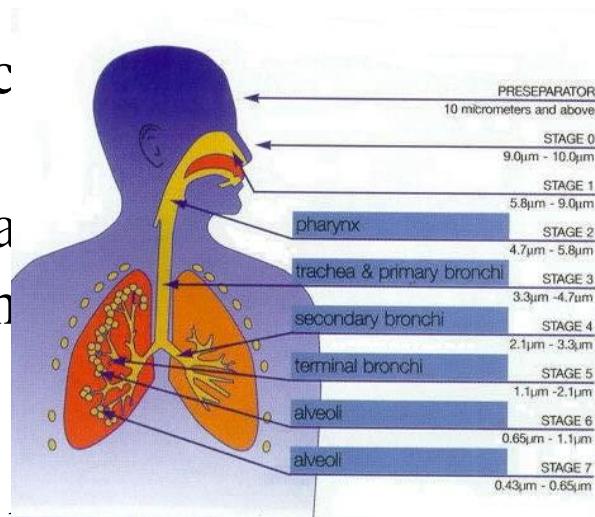

- Chemistry of the ozone hole is heterogeneous c
ice particles
- Formation of acidity in the marine boundary la
chemistry in the aqueous phase provided by hum
particles

Climate:

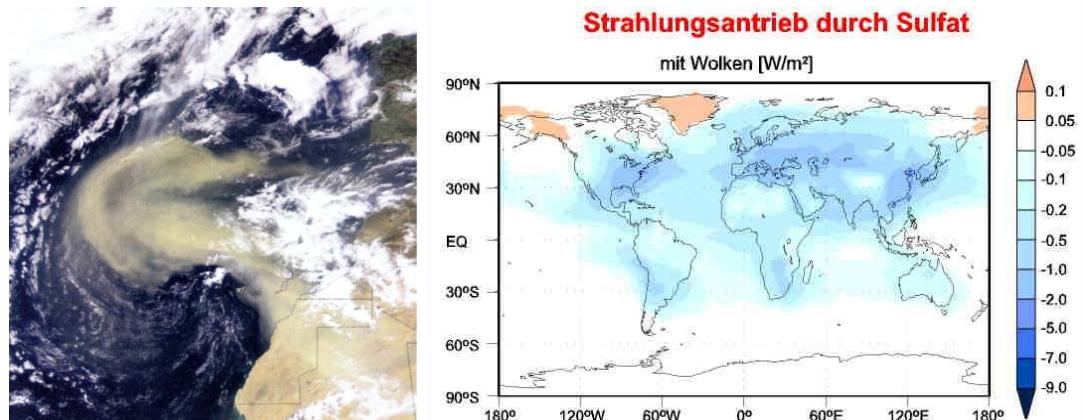

- strong climate sensitivity to aerosols, direct and more so
indirect

Toxicology:

- fine particles $< 10 \mu\text{m}$ (PM_{10}) reach the lung
- constituents are partly toxic

Relevance of aerosols: Climate

Sulfate aerosols: cooling
(Feichter & Lammel, 1999)

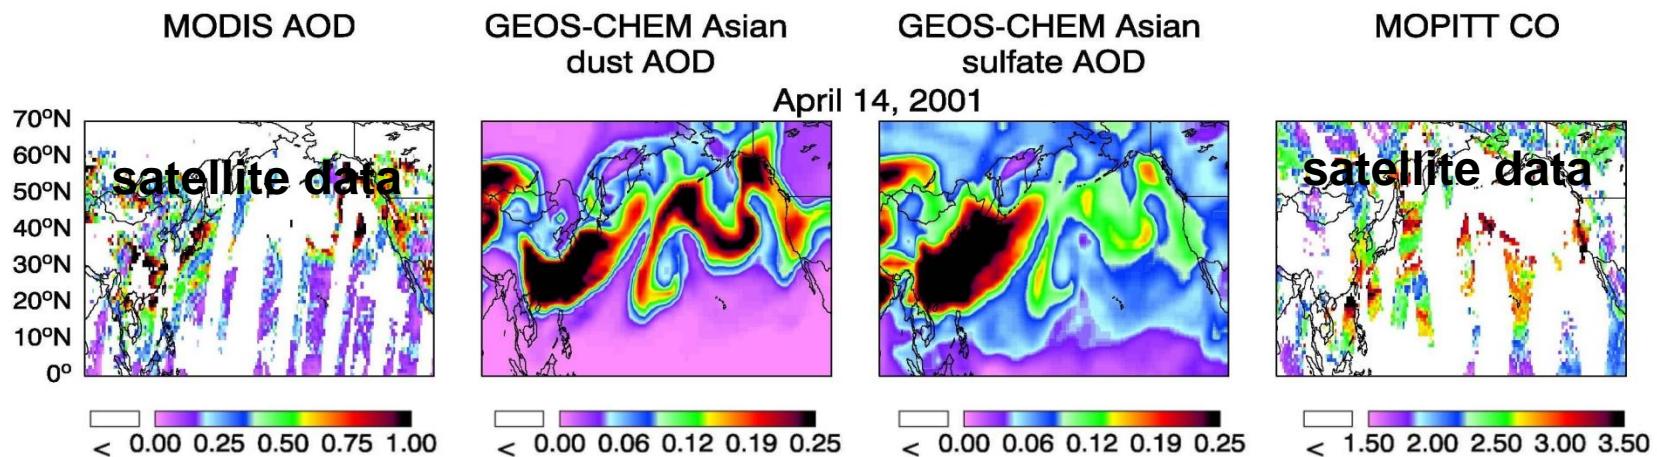

Optical and hygroscopic properties

- Scattering (‘direct effect’) + warming due to absorption (‘semi-direct effect’):
 -1.2 W/m^2 (earth surface)
- Clouds: increase optical thickness and albedo due to increased droplet number concentration: $-1.5 \text{ to } 0.5 \text{ W/m}^2$ (Lohmann & Feichter, 2001; Lohmann et al., 2001)

DUST STORMS PROVIDE VISIBLE EVIDENCE OF INTERCONTINENTAL TRANSPORT OF AEROSOLS

Glen Canyon, AZ/USA

Jacob, Heald et al., Harvard Univ., 2004

PROVEN PATHWAYS OF REGIONAL AND INTERCONTINENTAL TRANSPORT OF AEROSOLS

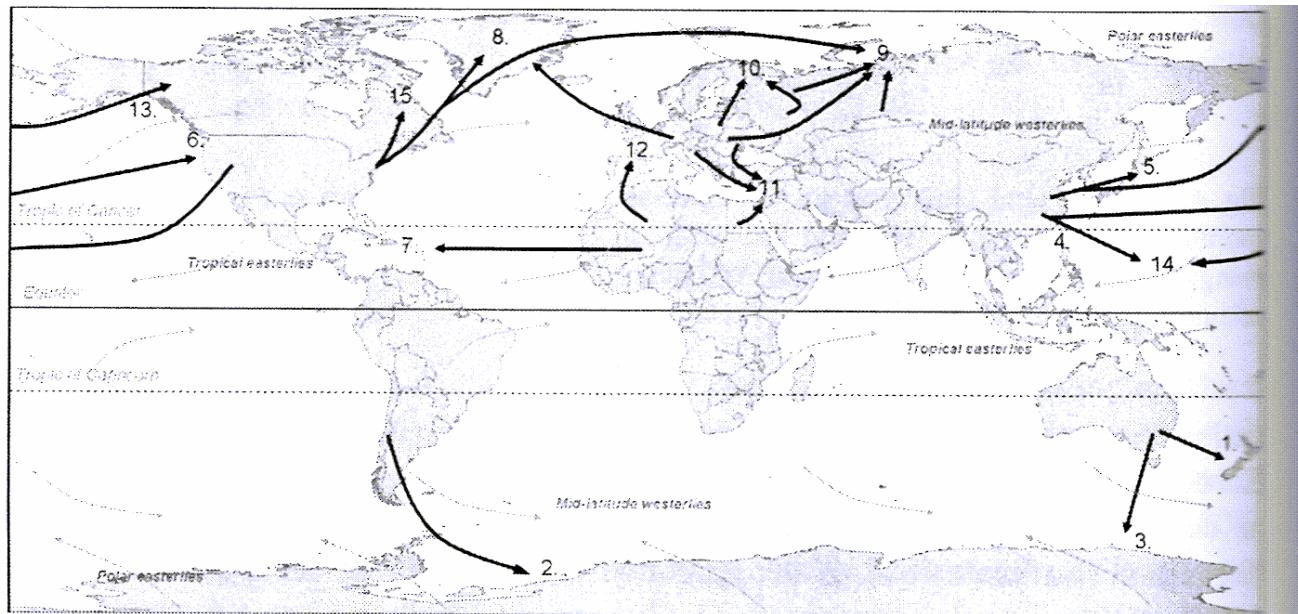

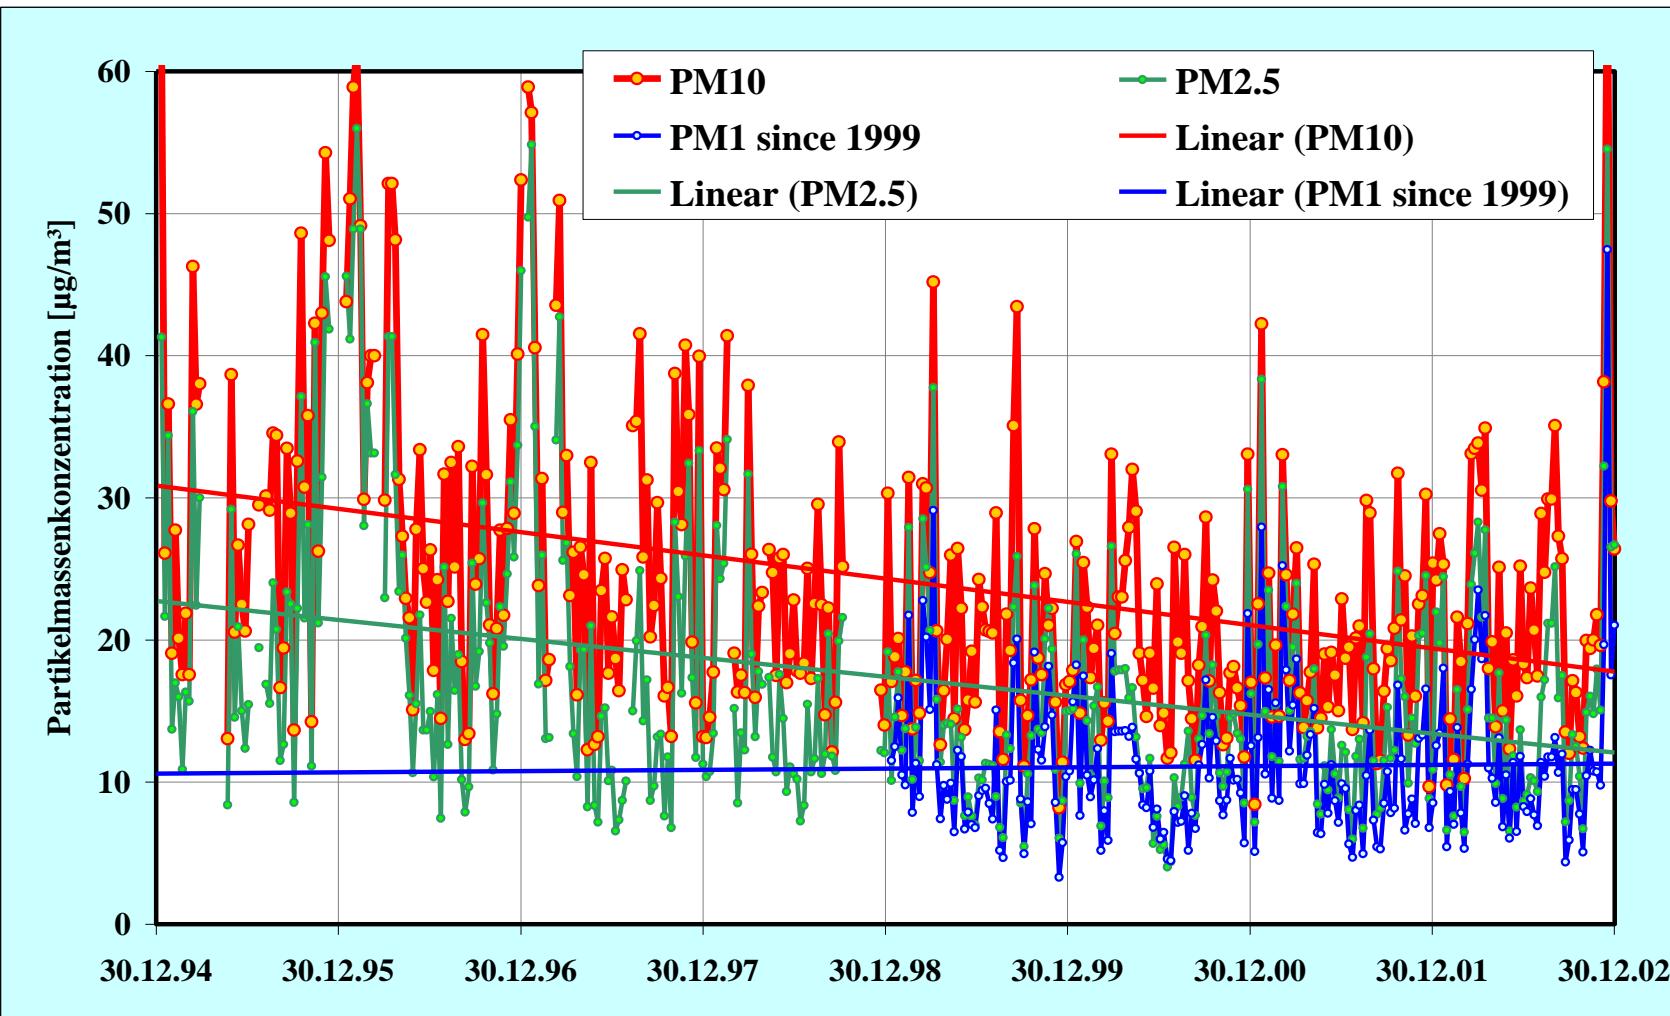

Fig. 5 The major documented pollution plume pathways over which the long-range transport of pollution occurs (as indicated by the *black arrows*). The main windfields are also indicated on the figure by the *grey arrows*. The *numbers* on the figure refer to representative studies documenting pollution transport over these pathways. 1 Australia to New Zealand (Marx et al. 2008); 2 South America to Antarctica (Wolff et al. 1999); 3 Australia to Antarctica (Vallelonga et al. 2002); 4 Asia to Taiwan (Lin 2001); 5 Asia to Japan and Korea (Kim et al. 2009; Okuda et al. 2006); 6 Asia to North America (Jaffe et al. 2003; Osterberg et al. 2008); 7 northern Africa to central America (Arimoto et al. 1992); 8 Europe and North America to Greenland (Hong et al. 1996; McConnell and Edwards 2008); 9 North America, Europe and Russia to the Russian Arctic (Shevchenko et al. 2003); 10 western and eastern Europe to Scandinavia (Brånnvall et al. 1999); 11 Europe and North Africa to the Middle East (Erel et al. 2007); 12 North Africa to Spain (Bacardit and Camarero 2009); 13 Asia to the North American Arctic (Osterberg et al. 2008); 14 Asia and North America to the central north Pacific (Settle and Patterson 1982); 15 North America to the remote Canadian Arctic (Outridge et al. 2002)

Particle growth downwind of NH₃ sources:

- plumes downwind < 300 m of open liquid manure pits and other more or less open sources (animal houses, feed stocks)
- sub- μm size range: $\Delta n_{\text{CN}} = +(8-18) \cdot 10^3 \text{ cm}^{-3}$
- super- μm size range: very significant around 2 μm , $\Delta n_{1-4\mu\text{m}} = 14-21 \text{ cm}^{-3}$
- under humid conditions ((1) r.h. = 90%, T = 6-9 °C; rh \approx rh_D((NH₄)₂SO₄) and rh > rh_D(NH₄NO₃)) growth rate 0.2-0.7 $\mu\text{m min}^{-1}$

strong temperature dependence of phase equilibrium $\text{NH}_3 + \text{HNO}_3 =$
for $\text{rh} < \text{rh}_D$:

$$\begin{aligned} p_{\text{NH}_3} * p_{\text{HNO}_3} = & \quad 0.12 \text{ ppbv}^2 (278 \text{ K}), \\ & \quad 2.0 \text{ ppbv}^2 (288 \text{ K}), \\ & \quad 28 \text{ ppbv}^2 (298 \text{ K}) \end{aligned}$$

$Y = [\text{NH}_4\text{NO}_3] / \{[\text{NH}_4\text{NO}_3] + 3[\text{NH}_4(\text{SO}_4)_2]\}$
Humidity dependence:
(Stelson & Seinfeld, 1982)

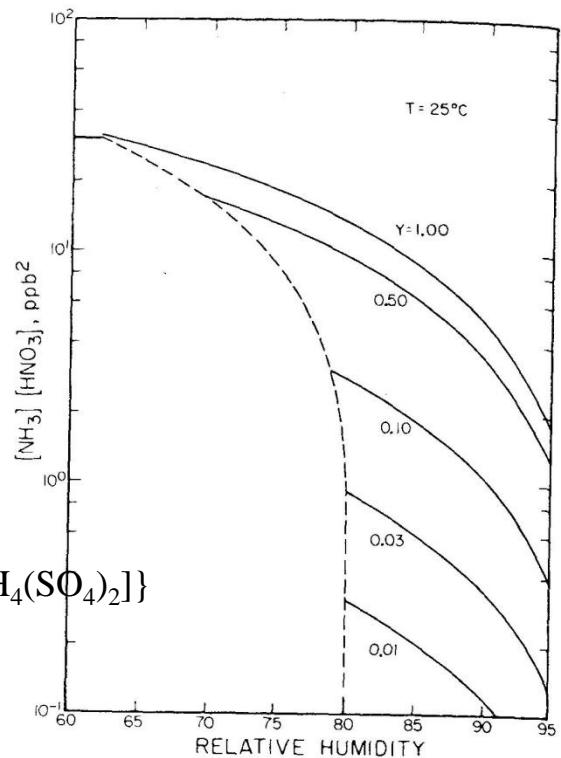

Fig. 2. The effect of $(\text{NH}_4)_2\text{SO}_4$ on the relative humidity dependence of the NH_4NO_3 dissociation constant.

Ions volatile, and non-volatile:

Winter

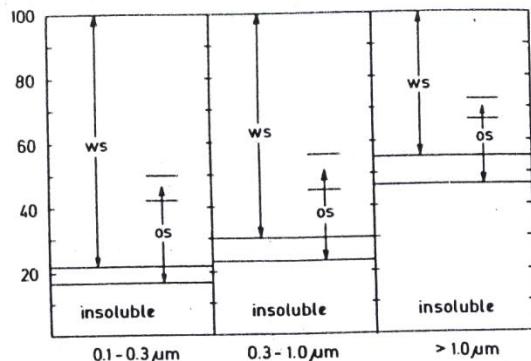

Summer

A large fraction of the organic carbon (OC, POM) is water soluble (WSOC)

(...and, hence, suitable as cloud condensation nucleus (CCN))

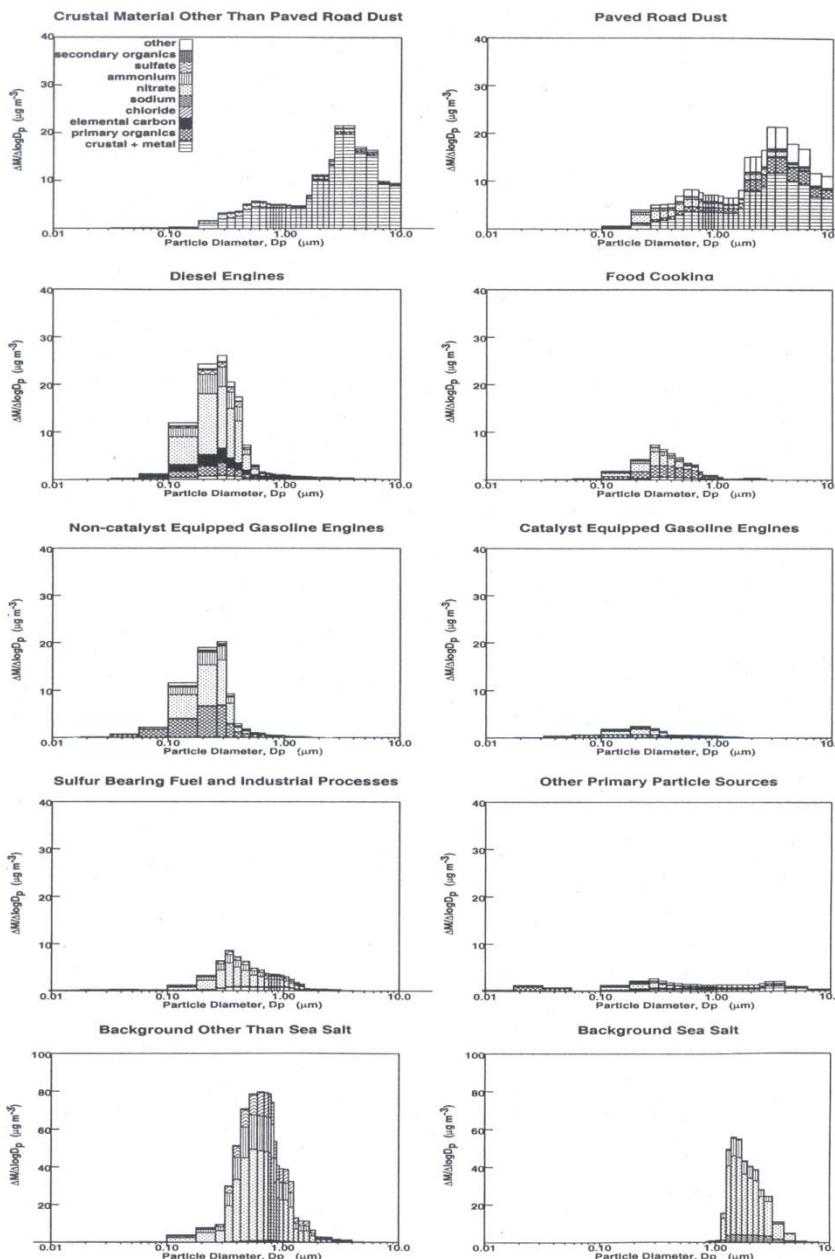

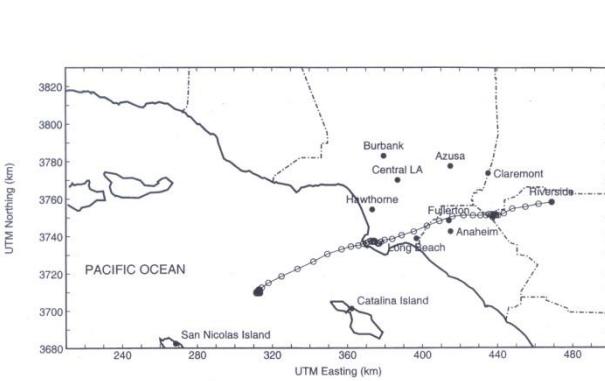

Continental aerosol (Winkler, 1974)

Continental aerosol consists of (each 25-50%):

- aliphatic polyols (mostly sugars) and polyethers (polyphenols)
- low-molecular aliphatic and other multifunctional compounds, e.g. $R(COOH)_{1-2}$
- unsaturated aliphatic and aromatic polyacids of various lipophilicity („humic-like“), $M = 200-500$ Da, sources: Oxidation of soot, acid catalyzed polymerisation of terpenes (Havers et al., 1998; Fuzzi et al., 2001; Krivacsy et al., 2001; Decesari et al., 2002; Gelencser et al., 2003; Puxbaum et al., 2003)

Aerosol sources, size segregated

Air in Riverside, CA, 25.9.1996 (Kleeman et al., 1999)

- Emission inventory (source distribution, characteristics)
- Atmosphere model covering transport and transformations

Source contributions to OC: urban

Total fine part. OC emitt. 30 t/d

Meat cooking 21%

Road abrasion 16%

Open fires 14%

Vehicles without cat.
converter 12%

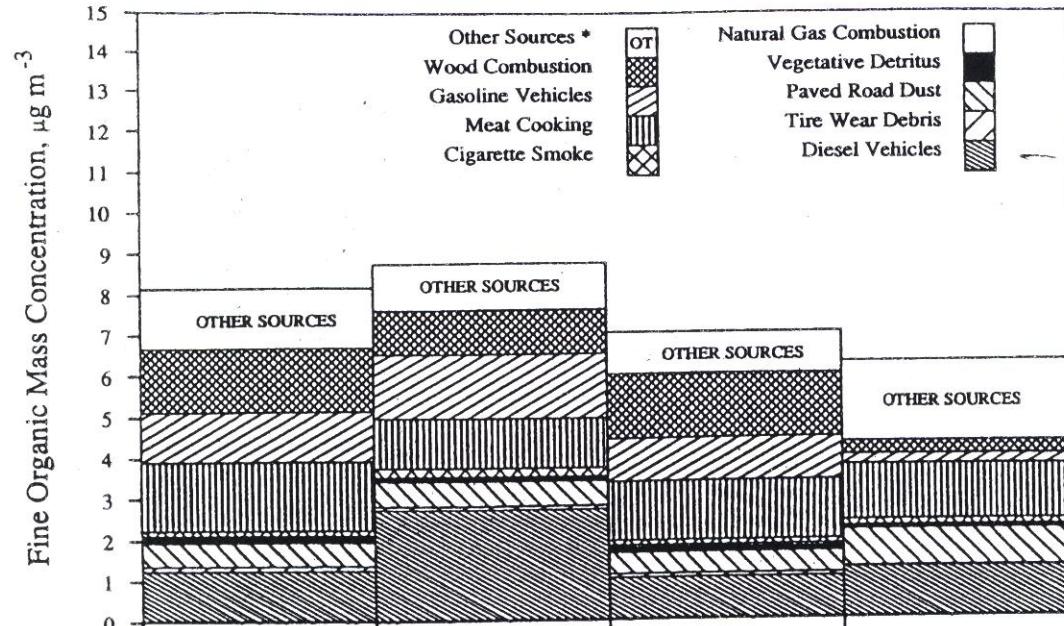

Diesel vehicles 6.2%

Lacquing 4.8%

Forest fires 2.9%

Vehicles without cat.
converter 2.9%

Tobacco smoke 2.7%

* Other Sources include secondary formation

Table 4. Source apportionment of fine particulate mass concentration: 1982 annual average determined by chemical mass balance (avg ± std in $\mu\text{g m}^{-3}$)

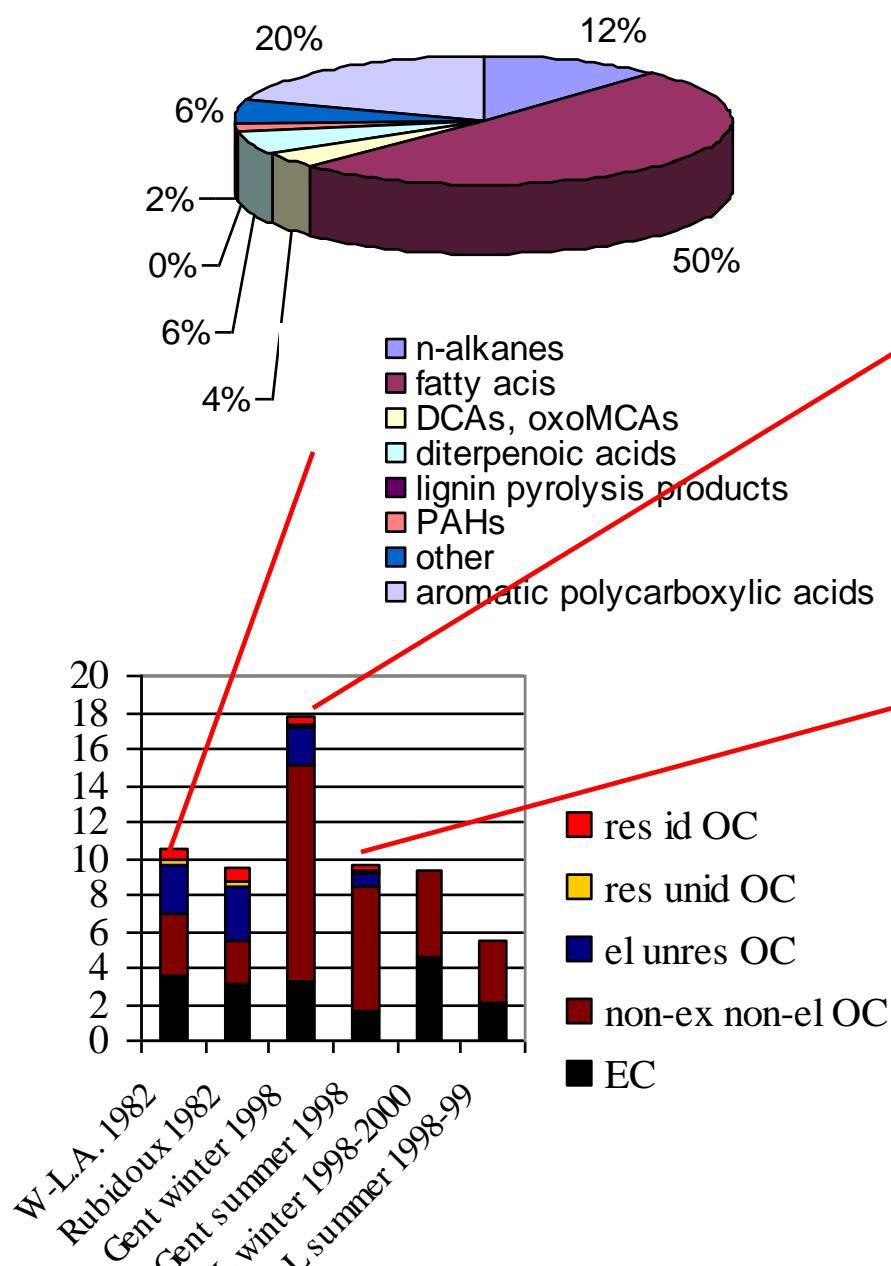

Source	Pasadena	Downtown LA	West Los Angeles	Rubidoux
Diesel exhaust	5.27 ± 0.72	11.6 ± 1.19	4.36 ± 0.64	5.35 ± 0.51
Tire wear debris	0.29 ± 0.11	0.22 ± 0.09	0.25 ± 0.09	
Paved road dust	3.46 ± 0.43	3.62 ± 0.46	3.00 ± 0.39	5.50 ± 0.61
Vegetative detritus	0.33 ± 0.10	0.24 ± 0.12	0.38 ± 0.11	0.18 ± 0.08
Natural gas combustion aerosol	0.047 ± 0.02	0.040 ± 0.019	0.034 ± 0.016	0.029 ± 0.008
Cigarette smoke	0.18 ± 0.03	0.26 ± 0.045	0.20 ± 0.028	0.19 ± 0.032
Meat charbroiling and frying	2.41 ± 0.46	1.74 ± 0.34	2.03 ± 0.39	1.94 ± 0.35
Catalyst and non-catalyst gasoline-powered vehicle exhaust	1.63 ± 0.20	2.12 ± 0.23	1.44 ± 0.16	0.34 ± 0.05
Wood smoke	2.70 ± 0.43	1.85 ± 0.31	2.65 ± 0.41	0.54 ± 0.10
Organics (other + secondary)	1.46 ± 0.66	1.16 ± 0.76 ^b	1.03 ± 0.71 ^b	1.94 ± 0.44
Sulfate ion (secondary + background)	5.9 ± 0.60	6.6 ± 0.65	5.9 ± 0.60	5.8 ± 0.51
Secondary nitrate ion	2.1 ± 0.27	3.0 ± 0.54	1.9 ± 0.29	10.4 ± 1.2
Secondary ammonium ion	2.6 ± 0.34	3.0 ± 0.37	2.3 ± 0.23	5.1 ± 0.59
Sum	28.3 ± 1.5	35.5 ± 1.9	25.3 ± 1.4	37.3 ± 1.8
Measured	28.2 ± 1.9	32.5 ± 2.8	24.5 ± 2.0	42.1 ± 3.3

^a Not statistically different from zero with greater than 95% confidence, and therefore removed from CMB model.

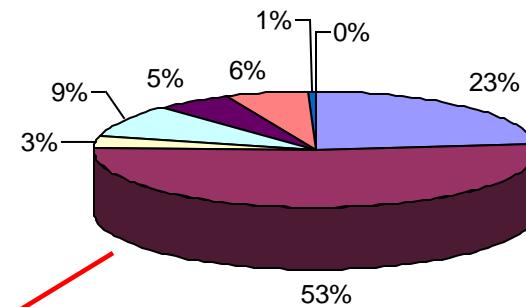

^b Not statistically different from zero with greater than 95% confidence.
