

# Temperature

„Populační ekologie živočichů“

Stano Pekár

# Effect of conditions

- ▶ all conditions affect population growth via controlling metabolic processes in ectotherms
- ▶ temperature, humidity, day length, pH, etc.

# Universal effect of temperature

- ▶ temperature affects population growth of ectotherms
- ▶ physiological time – combination of time and temperature
- ▶ rate of metabolism increases approx. by 2.5x for every 10 °C

$$Q_{10} = 2.5$$

- ▶ universal temperature dependence:

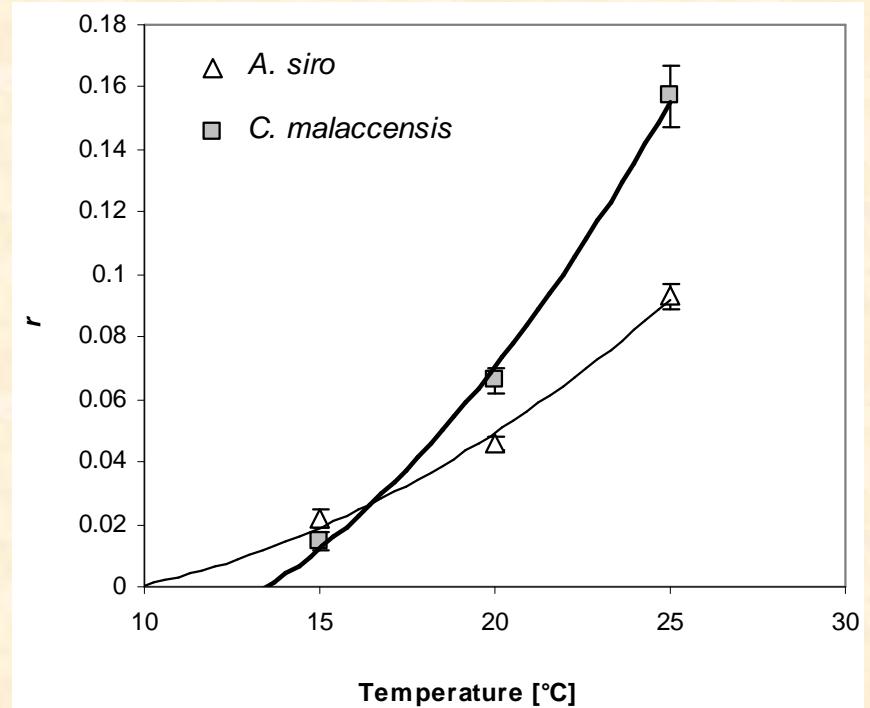

- rate of metabolism  $B$ : 
$$B \sim e^{-\beta/T}$$

- rate increases with body mass ( $M$ ):

$$B \sim M^{3/4}$$

- biological time  $t_b$ :

$$t_b \sim M^{3/4} e^{-\beta/T}$$

# Linear model

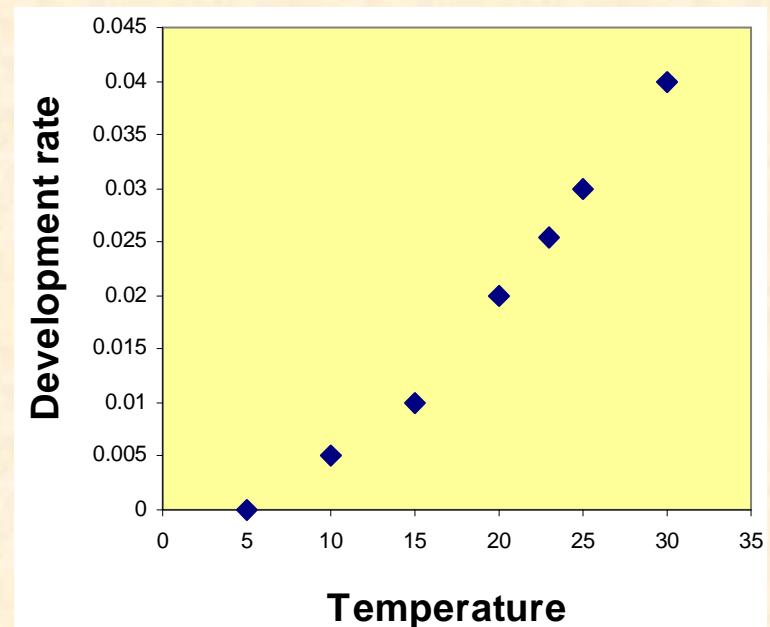

- ▶ model is based on the assumption that development rate is a linear function of temperature  $T$
- ▶ valid for the region of moderate temperatures (15-25°)
- ▶ at low temperatures organisms die due to coldness

$D$  .. development time (days)

$v$  .. rate of development =  $1/D$

$T_{\min}$  .. lower temperature limit

- temperature at which  
development rate = 0

$ET$  .. effective temperature .. developmental temperature between  $T$  and  $T_{\min}$   
 $S$  .. sum of effective temperature .. number of degree-days [ $^{\circ}\text{D}$ ] required to complete development

.. does not depend on temperature =  $D * ET$

$T_{\min}$  and  $S$  can be estimated from the regression line of  $v = a + bT$

$T_{\min} :$

$$a + bT = 0$$

$$T_{\min} = -\frac{a}{b}$$

$$S : \quad S = D(T - T_{\min}) = D\left(T + \frac{a}{b}\right)$$

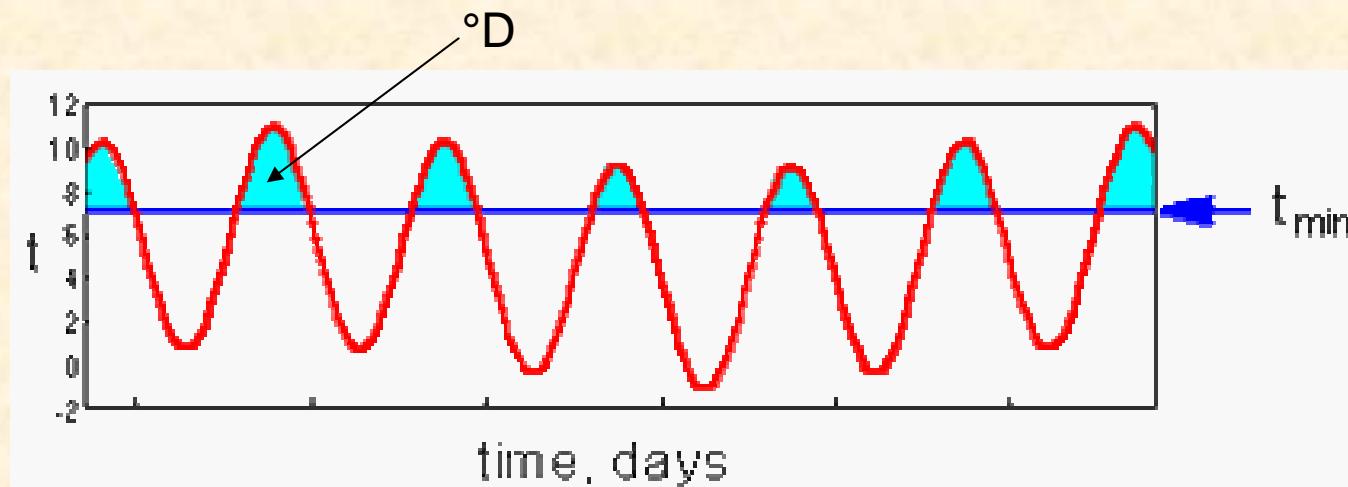

$$D = \frac{1}{v} = \frac{1}{a + bT}$$

$$S = \frac{T + \frac{a}{b}}{a + bT}$$

$$S = \frac{1}{b}$$

- ▶ sum of effective temperature ( $S$ ) [ $^{\circ}\text{D}$ ] is equal to area under temperature curve restricted to the interval between current temperature ( $T$ ) and  $T_{\min}$
- ▶ biofix .. the date when degree-days begin to be accumulated

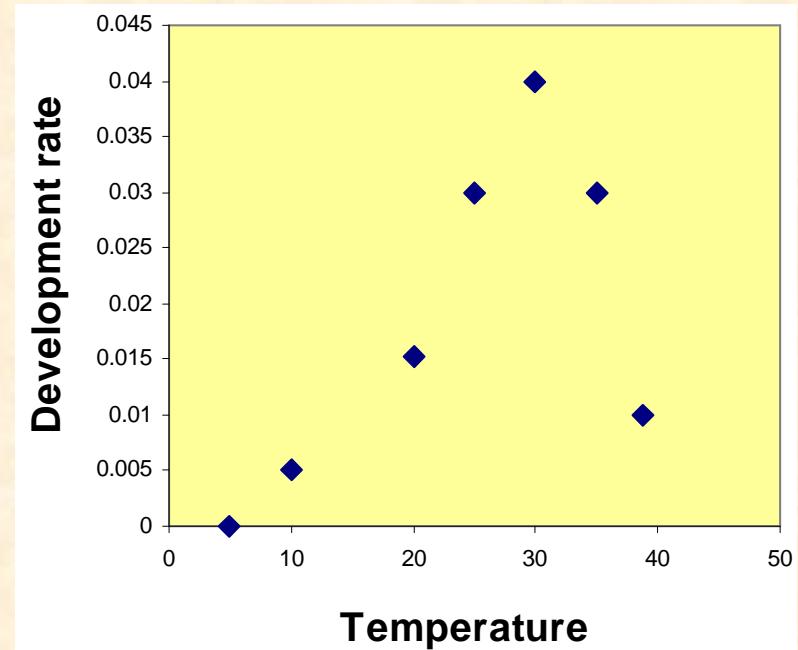

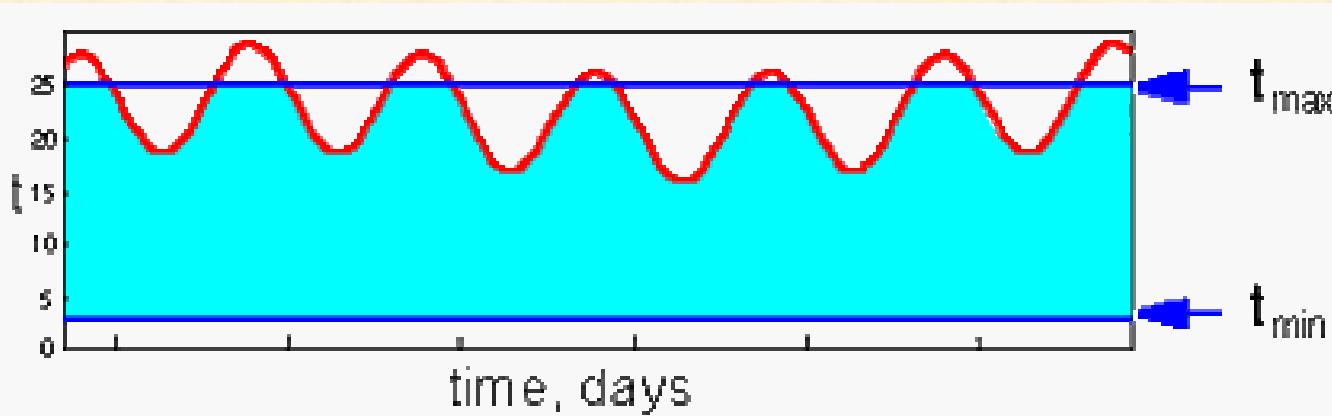

$$S = \sum_{i=1}^n T - T_{\min}$$

# Non-linear models

- ▶ when development rate is a non-linear function of temperature
- ▶ *ET..* developmental temperature between  $T_{\min}$  and  $T_{\max}$
- ▶ at high temperatures organisms die due to overheating

$T_{\max}$  .. upper temperature threshold  
- temperature at which  
development rate = 0

- ▶ several different non-linear models (Briere, Lactin, etc.)
- ▶ allow to estimate  $T_{\min}$ ,  $T_{\max}$  and  $T_{\text{opt}}$  (optimum temperature)
- ▶ easy to interpret for experiments with constant temperature
- ▶ instead of using average day temperature, use actual temperature

Briere et al. (1999)

$$v = a \times T \times (T - T_{\min}) \times \sqrt{T_{\max} - T}$$

$v$  .. rate of development ( $=1/D$ )

$T$  .. experimental temperature

$T_{\min}$  .. low temperature threshold

$T_{\max}$  .. upper temperature threshold

$a$  .. unknown parameter

Optimum temperature:

$$t_{opt} = \frac{4T_{\max} + 3T_{\min} + \sqrt{16T_{\max}^2 + 9T_{\min}^2 - 16T_{\min}T_{\max}}}{10}$$

- parameters are estimated using non-linear regression

Lactin et al. (1995)

$$v = e^{\rho T} - e^{(\rho T_m - \frac{T_m - T}{\Delta})} + \phi$$

$v$  .. rate of development

$T$  .. experimental temperature

$T_m, \Delta, \rho, \phi$  .. unknown parameters

$T_{\max}$  and  $T_{\min}$  can be estimated from the formula:

$$0 = e^{\rho T} - e^{(\rho T_m - \frac{T_m - T}{\Delta})} + \phi$$

$T_{\text{opt}}$  can be estimated from the first derivative:

$$\frac{\partial v(T)}{\partial T} = \rho e^{\rho T} - \frac{1}{\Delta} e^{\rho T_m - \frac{T_m - T}{\Delta}}$$
