# Identification of the role of *ARR21* gene – homology of *ARR* genes

## Legenda:

- ARR-A
- ARR-B
- nalezena alespoň jedna EST

# Identification of the role of *ARR21* gene – causes of absence of the phenotype

- Functional redundancy within the gene family?
- Phenotype only in very specific conditions (?)

INVESTICE DO ROZVOJE VZDĚLÁVÁNÍ

Tato prezentace je spolufinancována  
Evropským sociálním fondem  
a státním rozpočtem České republiky

# Identification of the role of *ARR21* gene – summary

- Gene *ARR21* identified by comparative analysis of *Arabidopsis* genome
- Based on sequence analysis, its function was predicted
- Site-specific expression of *ARR21* gene was proved at the RNA-level
- Identification of gene function by insertional mutagenesis in case of *ARR21* in development of *Arabidopsis* was not successful, probably because of functional redundancy within the gene family

INVESTICE DO ROZVOJE VZDĚLÁVÁNÍ

Tato prezentace je spolufinancována  
Evropským sociálním fondem  
a státním rozpočtem České republiky

# Outline

- Forward and reverse genetics approaches
  - Differences between the approaches used for identification of genes and their function
- Identification of genes *ab initio*
  - Structure of genes and searching for them

# Structure of genes

- promoter
- transcription start
- 5'UTR
- translation start
- splice sites
- stop codon
- 3'UTR
- polyadenylation signal

# RNA splicing

INVESTICE DO ROZVOJE VZDĚLÁVÁNÍ

Tato prezentace je spolufinancována  
Evropským sociálním fondem  
a státním rozpočtem České republiky

# Identification of genes *ab initio*

- Omitting 5' a 3' UTR
- Identification of translation start (ATG) and stop codon (TAG, TAA, TGA)
- Finding donor (typically GT) and acceptor (AG) splice sites
- Many ORFs are not true coding sequences – in *Arabidopsis*, there are on average approximately 350 million ORFs in every 900 bp of sequence(!)
- Using various statistic models (e.g. Hidden Markov Model – HMM, see recommended literature, Majoros *et al.*, 2003) to evaluate and score the weight of identified donor and acceptor sites

INVESTICE DO ROZVOJE VZDĚLÁVÁNÍ

Tato prezentace je spolufinancována

## SplicePredictor

- a method to identify potential splice sites in (plant) pre-mRNA by sequence inspection using Bayesian statistical models
- (click [here](#) to access the older method using logitlinear models)

Sequences should be in the one-letter-code ( $\{a,b,c,g,h,k,m,n,r,s,t,u,w,y\}$ ), upper or lower case; all other characters are ignored during input. Multiple sequence input is accepted in **FASTA** format (sequences separated by identifier lines of the form “>SQ;name\_of\_sequence comments”) or in **GenBank** format.

Paste your genomic DNA sequence here:

```
GAGGAGGCACAAATGACGAATATACAAAATGATCTTAAACAGCTAAACTATATTGGACATTTTCGATCTCAGATATA
AAAGATTTCATTCAATATAATACCTGGATAAAACTCTTATTATTTCTTAGTTATTAAAAAAACCTCTAATAAAT
ACGAGTTAACGTCCACAAATCGCTTAGACTAAAATACACCATATAATTCAAACGATAAGTTACAAAGTAATATCC
AAGTATCTCATAGTCAACATATATAGTAAATAATTAGTTGACGTATAAGAAAATAAAATAAATTAGTATCTTAT
TTTGGGTGGTGCTGACTGGTGACTGGCTGAGAATGCTCGGAAATGGAACCATAATCCAAGACATGGTTTAGAT
```

... or upload your sequence file (specify file name):

... or type in the GenBank accession number of your sequence:

# Splice site prediction

## What do the output columns mean?

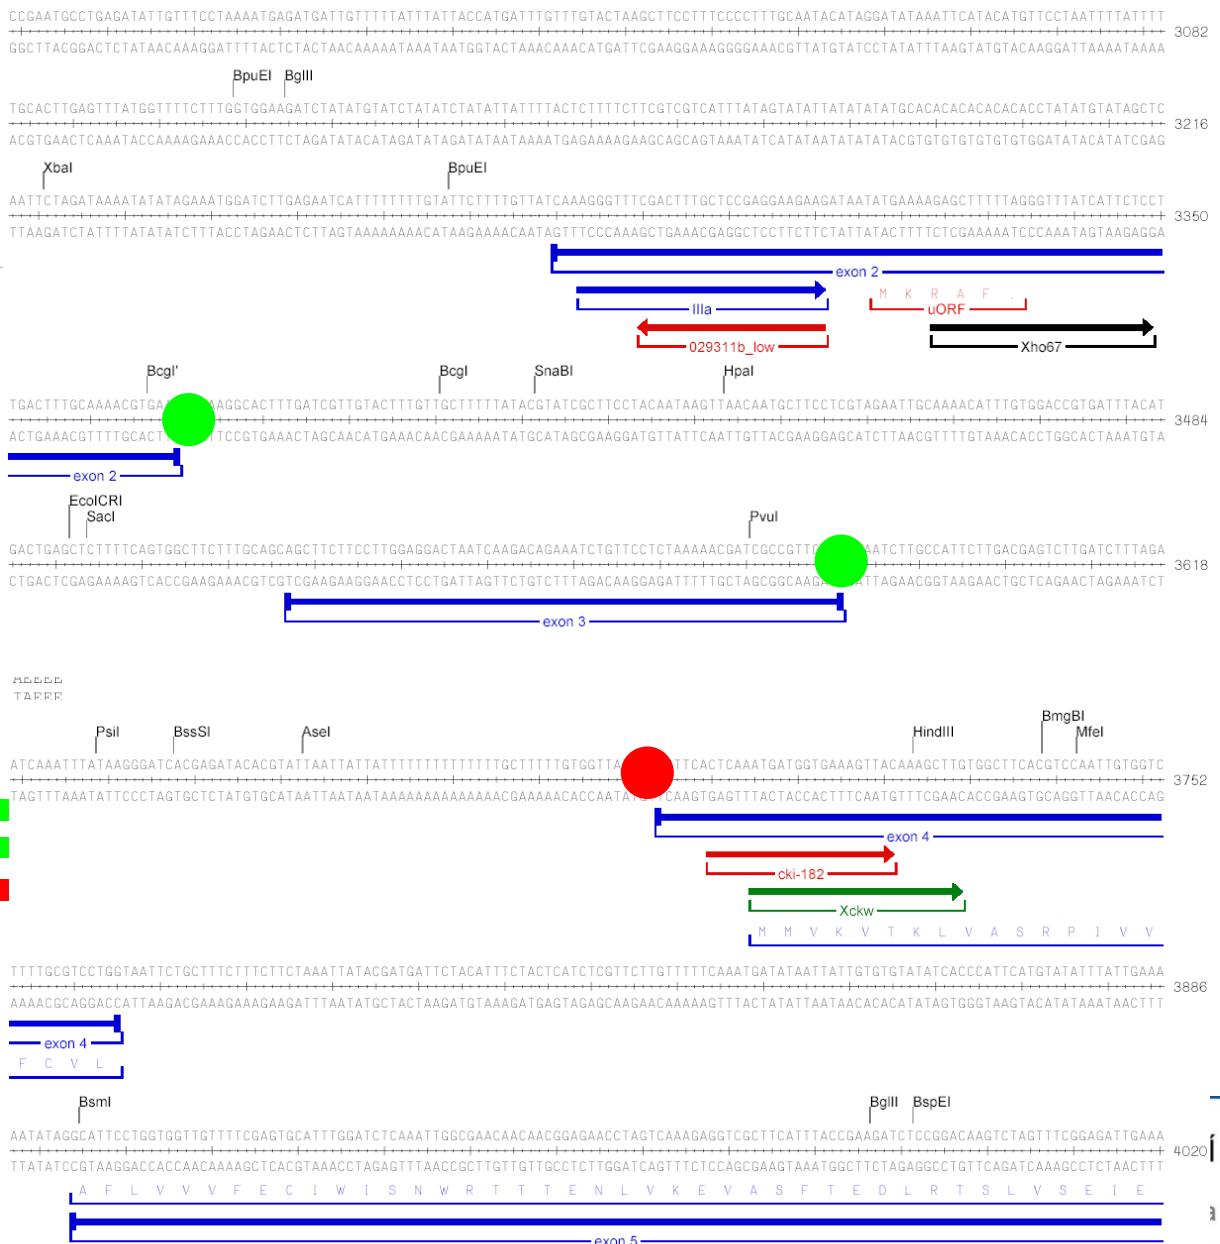

SplicePredictor. Version of February 13, 2005.  
Date run: Wed Nov 9 11:30:14 2005

Species: Homo sapiens  
Model: 2-class Bayesian  
Prediction cutoff (2 ln[BF]): 3.00  
Local pruning: on  
Non-canonical sites: not scored

Sequence 1: your-sequence, from 1 to 9490.

# RNA splicing and adaptation

- Divergencies at splice site recognition in plants in practice – example of developmental plasticity of (not only) plants
  - Identification of mutant with point mutation (transition G→A) exactly at the splice site at the 5' end of the 4th exon

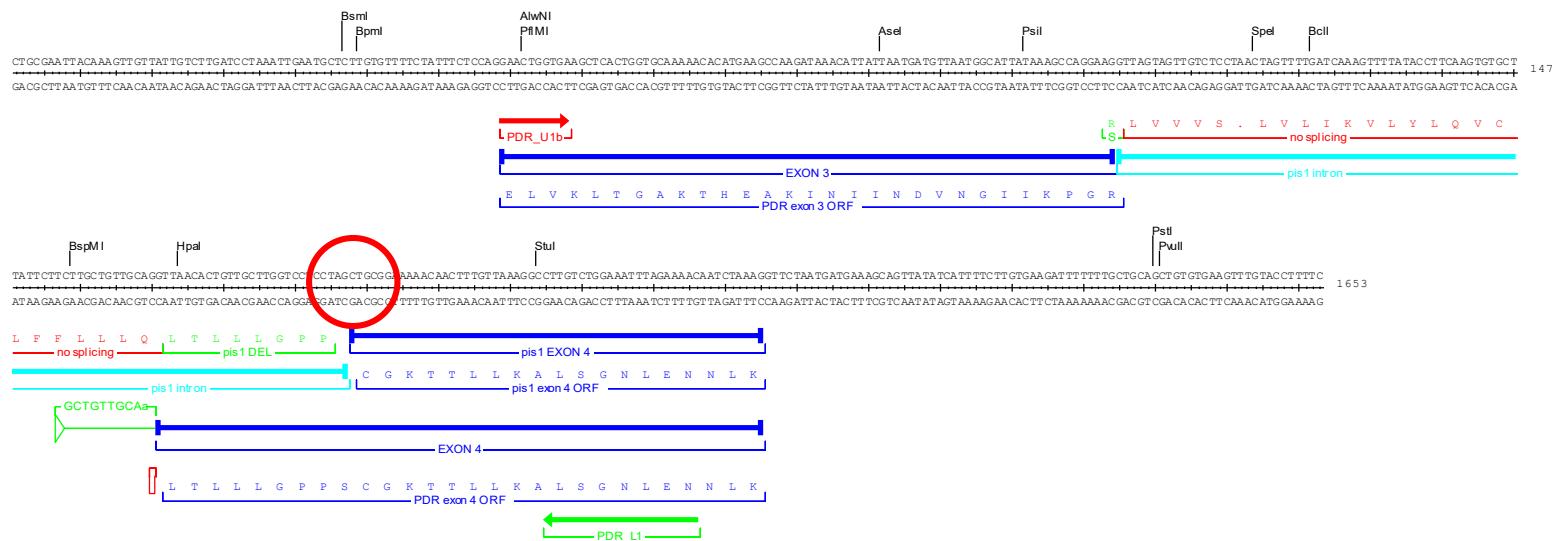

# RNA splicing and adaptation

- Identification of mutant with point mutation (transition G→A) exactly at the splice site at the 5' end of the 4th exon
- Analysis by RT PCR proved the presence of a fragment shorter than cDNA should be after the typical splicing event

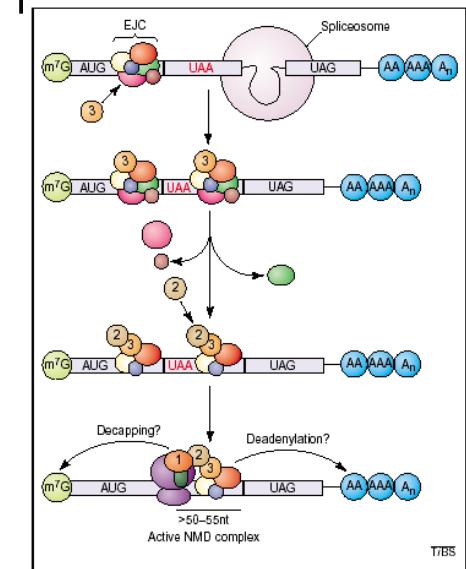

# RNA splicing and adaptation

- Divergencies at splice site recognition in plants in practice – example of developmental plasticity of (not only) plants
    - Identification of mutant with point mutation (transition G→A) exactly at the splice site at the 5' end of the 4th exon
    - Analysis by RT PCR proved the presence of a fragment shorter than cDNA should be after the typical splicing event
    - Sequenation of this fragment then suggested alternative splicing with the closest possible splice site in exon 4

# RNA splicing and adaptation

- Divergencies at splice site recognition in plants in practice – example of developmental plasticity of (not only) plants
  - Identification of mutant with point mutation (transition G→A) exactly at the splice site at the 5' end of the 4th exon
  - Analysis by RT PCR proved the presence of a fragment shorter than cDNA should be after the typical splicing event
  - Sequenation of this fragment then suggested alternative splicing with the closest possible splice site in exon 4
  - Existence of similar defense mechanisms was proven in different organisms as well (e.g. Instability of mutant mRNA with early stop codon formation (> 50 - 55 bp before typical stop codon) in eukaryotes, see recommended literature – Singh and Lykke-Andersen, 2003)

# Identification of genes *ab initio*

**The New GENSCAN Web Server at MIT**

**Identification of complete gene structures in genomic DNA**

For information about Genscan, click here

This server provides access to the program Genscan for predicting the locations and exon-intron structures of genes in genomic sequences from a variety of organisms.

This server can accept sequences up to 1 million base pairs (1 Mbp) in length. If you have trouble with the web server or if you have a large number of sequences to process, request a local copy of the program (see instructions at the bottom of this page) or use the [GENSCAN email server](#). If your browser e.g., Lynx) does not support file upload or multipart forms, use the [older version](#).

Organism:  Suboptimal exon cutoff (optional):

Sequence name (optional):

Print options: Predicted peptides only

Upload your DNA sequence file (one-letter code, upper or lower case, spaces/numbers ignored):

Or paste your DNA sequence here (one-letter code, upper or lower case, spaces/numbers ignored):

# Identification of genes *ab initio*

## GENSCANW output for sequence CKI1

GENSCAN 1.0 Date run: 10-Nov-105 Time: 02:24:26

Sequence CKI1 : 9490 bp : 36.53% C+G : Isochore 1 ( 0 - 43 C+G%)

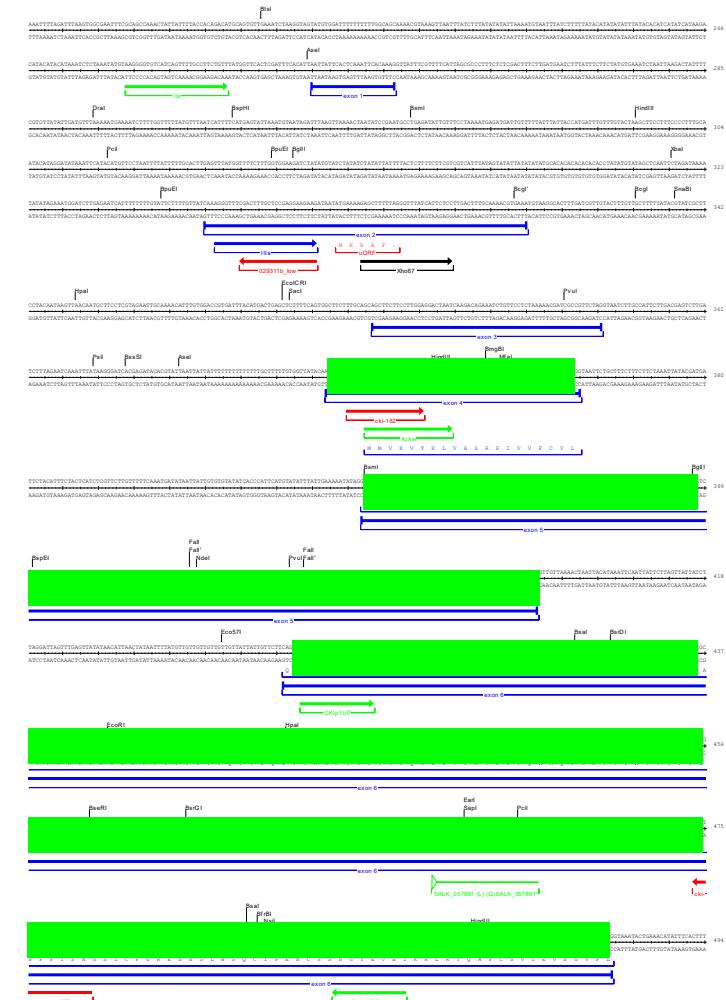

Parameter matrix: Arabidopsis.smat

Predicted genes/exons:

Gn.	Ex	Type	S	.Begin	...End	.Len	Fr	Ph	I/Ac	Do/T	CodRg	P....	Tscr..
1.00	Prom	+	1497	1536	40							-3.85

S.006	Intr	+	5442	6056	615	2	0	95	99	589	0.208	57.32

**Explanation Gn.Ex** : gene number, exon number (for reference) **Type** : Init = Initial exon (ATG to 5' splice site) Intr = Internal exon (3' splice site to 5' splice site) Term = Terminal exon (3' splice site to stop codon) Sngl = Single-exon gene (ATG to stop) Prom = Promoter (TATA box / initiation site) PlyA = poly-A signal (consensus: AATAAA) **S** : DNA strand (+ = input strand; - = opposite strand) **Begin** : beginning of exon or signal (numbered on input strand) **End** : end point of exon or signal (numbered on input strand) **Len** : length of exon or signal (bp) **Fr** : reading frame (a forward strand codon ending at x has frame  $x \bmod 3$ ). For example, if nucleotides 1,2,3 of the sequence are read as a codon, that's called reading frame 0. If 2,3,4 are read as a codon, that's reading frame 1. If 3,4,5 are read as a codon, that's reading frame 2, and so on. This information, together with the starting and ending positions of the exon, is sufficient to give the amino acid sequence encoded by the exon. Another use of the reading frame is that if you see two adjacent predicted exons separated by a relatively short intron which share the same reading frame, it may be worth looking at the possibility that the intervening intron is not correct, i.e. that the two exons plus the intervening intron might form one long exon (assuming there are no inframe stops in the intron, of course). **Ph** : net phase of exon (exon length modulo 3). For example, an exon of length 15 bp has net phase 0 since 15 is divisible by 3, an exon of length 16 bp has net phase 1 because 16 divided by 3 leaves a remainder of 1, an exon of length 17 bp has net phase 2, and an exon of length 18 bp has net phase 0 again. The point of this is that exons whose net phase is 0 can be omitted from the gene without disrupting the reading frame: such exons are candidates for being either 1) incorrect, or 2) alternatively spliced. **I/Ac** : initiation signal or 3' splice site score (tenth bit units;  $\times 10$ ). If below zero, probably not a real acceptor site. **Do/T** : 5' splice site or termination signal score (tenth bit units;  $\times 10$ ) If below zero, probably not a real donor site. **CodRg** : coding region score (tenth bit units) **P** : probability of exon (sum over all parses containing exon). This quantity is close to the actual probability that the predicted exon is correct. **Tscr** : exon score (depends on length, I/Ac, Do/T and CodRg scores).

**Comments** The SCORE of a predicted feature (e.g., exon or splice site) is a log-odds measure of the quality of the feature based on local sequence properties. For example, a predicted 5' splice site with score > 100 is strong; 50-100 is moderate; 0-50 is weak; and below 0 is poor (more than likely not a real donor site). The PROBABILITY of a predicted exon is the estimated probability under GENSCAN's model of genomic sequence structure that the exon is correct. This probability depends in general on global as well as local sequence properties, e.g., it depends on how well the exon fits with neighboring exons. It has been shown that predicted exons with higher probabilities are more likely to be correct than those with lower probabilities.

### **What are the suboptimal exons?**

Under the probabilistic model of gene structural and compositional properties used by GENSCAN, each possible "parse" (gene structure description) which is compatible with the sequence is assigned a probability. The default output of the program is simply the "optimal" (highest probability) parse of the sequence. The exons in this optimal parse are referred to as "optimal exons" and the translation products of the corresponding "optimal genes" are printed as GENSCAN predicted peptides. (All the data in our J Mol Biol paper and on the other GENSCAN web pages refer exclusively to the optimal parse/optimal exons.) Of course, the optimal parse does not always correspond to the actual (biological) parse of the sequence, that is, the actual set of exons/genes present. In addition, there may be more than one parse which can be considered "correct", for example, in the case of a gene which is alternatively transcribed, translated or spliced. For both of these reasons, it may be of interest to consider "suboptimal" ("near-optimal") exons as well, i.e. exons which have reasonably high probability but are not present in the optimal parse.

Specifically, for every potential exon E in the sequence, the probability  $P(E)$  is defined as the sum of the probabilities under the model of all possible "parses" (gene structures) which contain the exact exon E in the correct reading frame. (This quantity is calculated as described on the [GENSCAN exon probability page](#).) Given a probability cutoff C, suboptimal exons are those potential exons with  $P(E) > C$  which are not present in the optimal parse.

Suboptimal exons have a variety of potential uses. First, suboptimal exons sometimes correspond to real exons which were missed for whatever reason by the optimal parse of the sequence. Second, regions of a prediction which contain multiple overlapping and/or incompatible optimal and suboptimal exons may in some cases indicate alternatively spliced regions of a gene (Burge & Karlin, in preparation). The probability cutoff C used to determine which potential exons qualify as suboptimal exons can be set to any of a range of values between 0.01 and 1.00. The default value on the web page is 1.00, meaning that no suboptimal exons are printed. For most applications, a cutoff value of about 0.10 is recommended. Setting the value much lower than 0.10 will often lead to an explosion in the number of suboptimal exons, most of which will probably not be useful. On the other hand, if the value is set much higher than 0.10, then potentially interesting suboptimal exons may be missed.

# Identification of genes *ab initio*

GENSCAN predicted genes in sequence 02:56:23

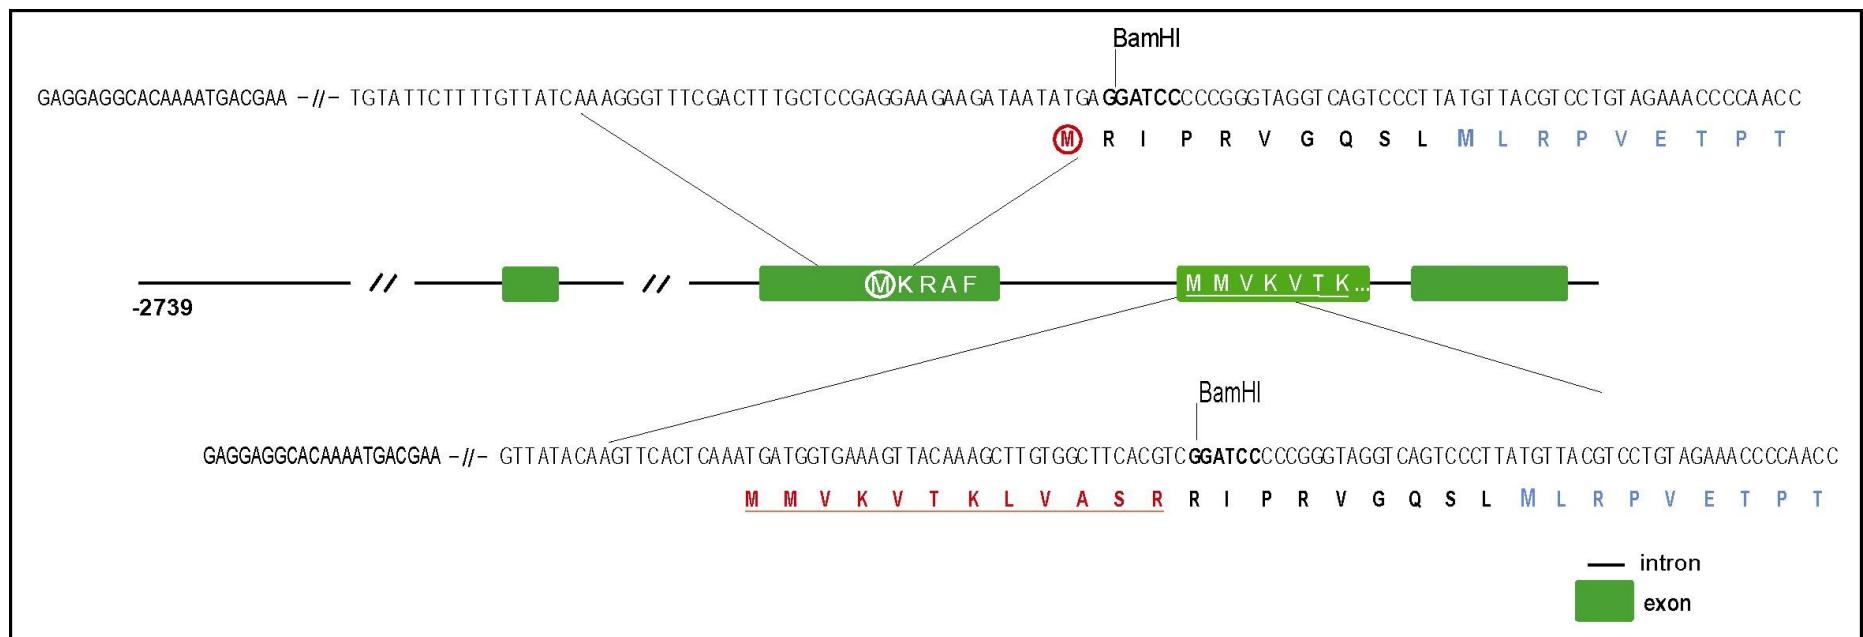

# Regulation of translation

- Functional purpose of splicing in untranslated regions – important regulation part of genes
- Translational repression by short ORFs in 5' UTR
- Identified e.g. in maize (Wang and Wessler, 1998, see recommended literature for additional info.)
- In case of CKI1 there was an attempt to prove this mechanism of regulation using transgenic lines carrying *uidA* under control of two versions of promoter (unconfirmed so far)

# Regulation of translation

- Functional purpose of splicing in untranslated regions – important regulation part of genes
- In case of CKI1 there was an attempt to prove this mechanism of regulation using transgenic lines carrying *uidA* under control of two versions of promoter (unconfirmed so far)

# Genomic homologies

- Searching for genes according to homologies
  - Comparison with EST databases
    - BLASTN (<http://www.ncbi.nlm.nih.gov/BLAST/>, <http://workbench.sdsc.edu/>)
  - Comparison with protein databases
    - BLASTX (<http://www.ncbi.nlm.nih.gov/BLAST/>, <http://workbench.sdsc.edu/>)
    - Genewise (<http://www.ebi.ac.uk/Wise2/>)

They compare protein sequence with genomic DNA (after reverse transcription), therefore the aminoacid sequence is needed
  - Comparison with homologous genome sequences from related species
    - VISTA/AVID (<http://www.lbl.gov/Tech-Transfer/techs/lbnl1690.html>)

# Genomic colinearity

- Genomes of related species (despite large differences) are characterized by analogies in sequence organization -> possibility to use this kind of information for identification of genes in related species when searching in databases
- General scheme of work while applying genomic colinearity (also called „comparative genomics“) for experimental identification of genes in related species:
  - **Mapping small genomes** using low-copy DNA markers (e.g. RFLP)
  - **Using these markers for identification of orthologous genes** (genes with the same or similar function) of related species
  - **Small genome** (e.g. rice, 466 Mbp) can be used as a **guide: molecular low-copy markers** (e.g. RFLP) **bound to gene of interest** are identified and these regions are then **used as a probe** for searching in **BAC libraries** during identification of **orthologous regions of large genomes** (e.g. barley: 5 Gbp, or wheat: 16 Gbp)

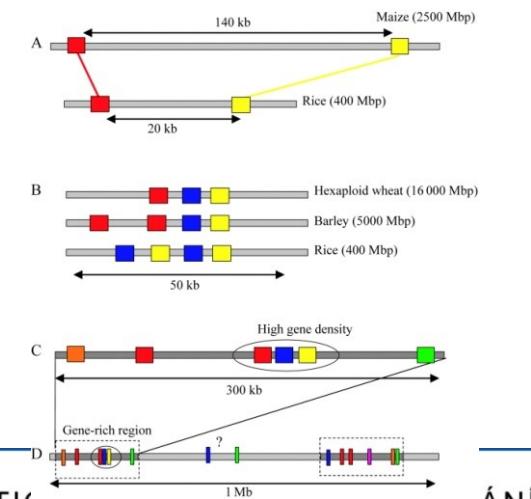

# Genomic colinearity

Feuillet and Keller, 2002

# Genomic colinearity

- Can be mostly used for the species of grass (e.g. using related genes of species of barley, wheat, rice, maize)
- Small genome reorganizations (deletions, duplications, inversions, translocations smaller than a few cM) are then detected by detailed sequential comparative analysis
- During evolution there's occurred some divergencies in related species, mostly in non-coding regions (invasion of retrotransposons etc.)

# Genomic colinearity

- Genomic colinearity of HOX genes in animals
  - Transcription factors controlling organisation of body in antero-posterior axis
  - Position of genes in genome corresponds with spatial expression during development
  - Interspecies conservation

Genomic organization of the *Capitella* sp. I Hox cluster. A total of 11 *Capitella* sp. I Hox genes are distributed among three scaffolds. Black lines depict two scaffolds, which contain 10 of the *Capitella* sp. I Hox genes. The eleventh gene, CapI-Post1, is located on a separate scaffold surrounded by ORFs of non-Hox genes (unpublished data). No predicted ORFs were identified between adjacent linked Hox genes. Transcription units are shown as boxes denoting exons, connected by lines that denote introns. Transcription orientation is denoted by arrows beneath each box. Color coding is the same as that used in on the right-hand side for each ortholog.

The phylogenetic tree on the right-hand side shows that the order of the genes on the chromosome is retained in several species (genome colinearity).

# Methylation filtration

- Preparation of gene-enriched libraries by technology of methylation filtration
  - genes are (mostly!) hypomethylated, noncoding regions are methylated
  - using bacterial restriction-modification system, which recognizes methylated DNA with restriction enzymes McrA a McrBC
    - McrBC recognizes methylated cytosin (in DNA), which comes after purine (G or A)
    - For cleavage the distance of these sites 40-2000 bp is necessary

INVESTICE DO ROZVOJE VZDĚLÁVÁNÍ
