## Measures of effect

- So far, x 2 test - testing whether there is an association between two proportions using a $2 \times 2$ (or $2 \times n$ ) table
- We are often interested in the relative difference between two proportions rather than the actual difference
- The effect estimates that we present are then ratios: there are three main measures we will use:
- Rate ratio
- Risk ratio
- Odds ratio

## Relative measures of effect (relative

 risk)We have 2 groups of individuals:

- An exposed group (group with risk factor of interest) and unexposed group (without such factor of interest)
- We are interested in comparing the amount of disease (mortality or other health outcome) in the exposed group to that in the unexposed group

## Risk/rate

- Measures the strengths of association between the risk factor and disease
- Incidence rate or Risk in exposed ( $r_{1}$ )
- Incidence rate or Risk in unexposed $\left(r_{0}\right)$

## Risk ratio

- we calculate the risk ratio (RR) as:

$$
R R=r_{1} / r_{0}
$$

## Risk difference

- the absolute difference between two risks (or rates)

$$
R D=r_{1}-r_{0}
$$

Example: cohort study of oral contraceptive use and heart attack

|  | Myocardial infarction |  |  |
| :---: | :---: | :---: | :---: |
|  | Yes | No | Total |
| OC use |  |  |  |
| Yes | 25 | 400 | 425 |
| No | 75 | 1500 | 1575 |
| Total | 100 | 1900 | 2000 |

Risk (exposed) $=25 / 425=0.059$
Risk (unexposed) $=75 / 1575=0.048$
Relative risk $=0.059 / 0.048=1.23$

- We can also have different strata of exposure. We may calculate ratio measures for each strata - we compare measure of frequency in each level with measure of frequency in the baseline (unexposed) level.
- Example: Death rates from CHD in smokers and non-smokers by age

| Age | Smokers <br> rate | Non- <br> smokers rate | Rate ratio |
| :--- | :---: | :---: | :---: |
| $35-44$ | 0.61 | 0.11 | $\mathbf{5 . 5}$ |
| $45-54$ | 2.40 | 1.12 | $\mathbf{2 . 1}$ |
| $55-64$ | 7.20 | 4.90 | $\mathbf{1 . 5}$ |
| $65-74$ | 14.69 | 10.83 | $\mathbf{1 . 4}$ |
| $75-84$ | 19.18 | 21.20 | $\mathbf{0 . 9}$ |
| $85+$ | 35.93 | 32.66 | $\mathbf{1 . 1}$ |
| ALL AGES | 4.29 | 3.30 | $\mathbf{1 . 3}$ |

What can you say about this table?

| Age | Smokers <br> rate | Non- <br> smokers rate | Rate ratio |
| :--- | :---: | :---: | :---: |
| $35-44$ | 0.61 | 0.11 | $\mathbf{5 . 5}$ |
| $45-54$ | 2.40 | 1.12 | $\mathbf{2 . 1}$ |
| $55-64$ | 7.20 | 4.90 | $\mathbf{1 . 5}$ |
| $65-74$ | 14.69 | 10.83 | $\mathbf{1 . 4}$ |
| $75-84$ | 19.18 | 21.20 | $\mathbf{0 . 9}$ |
| $85+$ | 35.93 | 32.66 | $\mathbf{1 . 1}$ |
| ALL AGES | 4.29 | $\mathbf{3 . 3 0}$ | $\mathbf{1 . 3}$ |

The rate ratio decreases with increasing age. It may suggest that the effect of smoking on the rate of CHD is higher in younger ages.

## Odds ratio

- Alternative measure of risk

The odds of disease is the number of cases divided by the number of non-cases Cases
Odds = ------------
Non cases
Odds ratio (OR) is ratio of odds of disease among exposed (odds ${ }_{\text {exp }}$ ) and odds of disease among unexposed (odds ${ }_{\text {unexp }}$ )

OR= odds exp $/$ odds $_{\text {unexp }}$

|  | Myocardial infarction |  |  |
| :---: | :---: | :---: | :---: |
|  | Yes | No | Total |
| OC use |  |  |  |
| Yes | 25 | 400 | 425 |
| No | 75 | 1500 | 1575 |
| Total | 100 | 1900 | 2000 |

We can calculate

- Odds (exposed) $\mathrm{O}_{\text {exp }}=25 / 400$
- Odds (unexposed) $\mathrm{O}_{\text {unexp }}=75 / 1500$
- Odds ratio $\mathrm{OR}=\mathrm{O}_{\exp } / \mathrm{O}_{\text {unexp }}=1.25$

## Odds ratio as an approximation to the risk ratio

- For a rare disease, odds ratio is approximately equal to the risk ratio (because denumerators are very similar)
- For a common conditions, OR overestimates the true RR

## Measures of population impact

- Population attributable risk (PAR) is the absolute difference between the risk (or rate) in the whole population and the risk or rate in the unexposed group

$$
P A R=r-r_{0}
$$

## Population attributable risk fraction (PARF or PAR\%)

- It is a measure of the proportion of all cases in the study population (exposed and unexposed) that may be attributed to the exposure, on the assumption of a causal association
- It is also called the aetiologic fraction, the percentage population attributable risk or the attributable fraction
- If $r$ is rate in the total population $\mathbf{P A F}=\mathbf{P A R} / \mathrm{r}$
PAR $=r-r_{0}$
PAF $=\left(r-r_{0}\right) / r$

## Risk or rate difference

Measure of the absolute effect
the absolute difference between two risks (or rates)

$$
R D=r_{1}-r_{0}
$$

Similar for rates $=$ rate difference $=$ incidence rate in exposed - incidence rate in unexposed

| Measure of <br> effect | Use of the measure | How to interpret results |
| :--- | :--- | :--- |
| Risk <br> Difference | Public Health <br> Interested in excess disease burden <br> due to factor ("Attributable risk") | Close to 0 = little effect <br> Large difference = large effect |
| Risk Ratio | Epidemiology <br> Causation <br> "This factor doubles the risk of the <br> disease" | Close to 1 = little effect <br> Large ratio = large effect <br> Close to 0 = large effect! |
| Odds Ratio | As for Risk Ratio <br> "This factor doubles the odds of the <br> disease" <br> Only possibility (case-control study) <br> More advanced statistical methods <br> (logistic regression) |  |

## Exercise

- 50 persons attended a garden party
- 25 of them developed diarrhoea in the next 3 days
- What was the risk of diarrhoea among the participants of the party?

## Exercise - cont.

- 30 party visitors had a BBQ (minced meat)
- 24 of them developed diarrhoea
- 20 people did not eat BBQ
- I of them developed diarrhoea
- How would you calculate RR related to eating BBQ?

## Exercise - cont.

- Risk among unexposed $\mathrm{R}_{0}$ :
- I/20
- Risk among exposed $\mathrm{R}_{1}$ :
- 24/30
- Relarive risk $R R=R_{1} / R_{0}=(24 / 30) /(1 / 20)=16$

## Summary of this part

I. Construct 2-way table to examine association between two categorical variables
2. Conduct Chi-squared test to assess the association between two categorical variables
3. Calculate measures of the effect for binary data

- Risk difference
- Risk ratio (relative risk)
- Odds ratio
