NANOMATERIALS

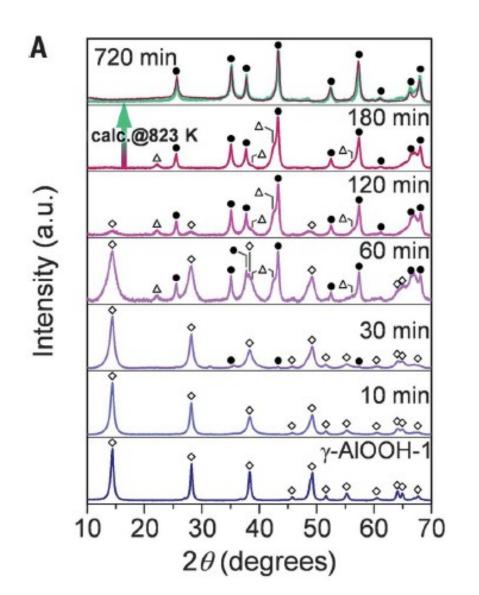

High-surface-area corundum by mechanochemically induced phase transformation of boehmite

Amol P. Amrute¹*, Zbigniew Łodziana², Hannah Schreyer¹, Claudia Weidenthaler¹, Ferdi Schüth¹*

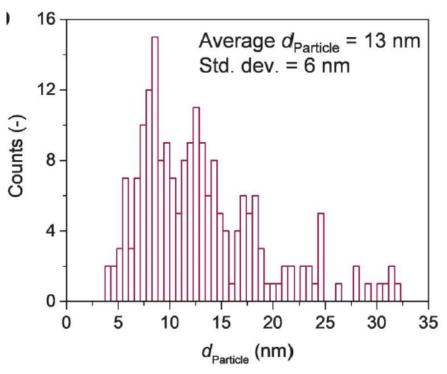

In its nanoparticulate form, corundum (α -Al₂O₃) could lead to several applications. However, its production into nanoparticles (NPs) is greatly hampered by the high activation energy barrier for its formation from cubic close-packed oxides and the sporadic nature of its nucleation. We report a simple synthesis of nanometer-sized α -Al₂O₃ (particle diameter ~13 nm, surface areas ~140 m² g⁻¹) by the mechanochemical dehydration of boehmite (γ -AlOOH) at room temperature. This transformation is accompanied by severe microstructural rearrangements and might involve the formation of rare mineral phases, diaspore and tohdite, as intermediates. Thermodynamic calculations indicate that this transformation is driven by the shift in stability from boehmite to α -Al₂O₃ caused by milling impacts on the surface energy. Structural water in boehmite plays a crucial role in generating and stabilizing α -Al₂O₃ NPs.

used. In a typical experiment, the milling vessel is charged with 1 g of precursor powder and milling balls in an open environment and placed in the vibration mill, followed by setting the milling frequency ($f_{\text{Mill}} = 20\text{-}30 \text{ Hz}$) and duration (t = 10-720 min). After milling for the desired period of time, the sample was recovered. For WC milling jar and

Brønsted acid sites based on penta-coordinated aluminum species

Zichun Wang¹, Yijiao Jiang², Olivier Lafon³, Julien Trébosc³, Kyung Duk Kim¹, Catherine Stampfl⁴, Alfons Baiker⁵, Jean-Paul Amoureux³ & Jun Huang¹

Zeolites and amorphous silica-alumina (ASA), which both provide Brønsted acid sites (BASs), are the most extensively used solid acid catalysts in the chemical industry. It is widely believed that BASs consist only of tetra-coordinated aluminum sites (AI^{IV}) with bridging OH groups in zeolites or nearby silanols on ASA surfaces. Here we report the direct observation in ASA of a new type of BAS based on penta-coordinated aluminum species (AI^{IV}) by ²⁷AI-{¹H} dipolar-mediated correlation two-dimensional NMR experiments at high magnetic field under magic-angle spinning. Both BAS-AI^{IV} and -AI^V show a similar acidity to protonate probe molecular ammonia. The quantitative evaluation of ¹H and ²⁷AI sites demonstrates that BAS-AI^{IV} co-exists with BAS-AI^{IV} rather than replaces it, which opens new avenues for strongly enhancing the acidity of these popular solid acids.

- Three types of interaction between support and active phase
 - Weak
 - Electrostatic
 - Covalent

- Weak interaction = Impregnation methods
 - Wet impregnation
 - Suspension of support (e.g. SiO₂ in water)
 - Solution of metal salt (e.g. Cu(NO₃)₂ in water)
 - Mixed together (suspension)
 - Cu²⁺ cations diffuse into the pores of SiO₂ support (=we need to wait for enough **long** time, Fick laws)
 - Drying, calcination (= formation of Cu₂O NPs on SiO₂), (reduction of Cu₂O to Cu NPs)
 - Disadvantages: Time, homogeneity.

- Weak interaction = Impregnation methods
 - Dry impregnation (Incipient wetness impregnation)
 - Dry support, pores full of gas (e.g. SiO₂ in ambient air)
 - Solution of metal salt, V = pore volume (e.g. Cu(NO₃)₂ in water)
 - Mixed together (paste)
 - Capillary elevation (fast) brings Cu²⁺ solution directly into the pores (concentration gradients might occur – pore size!)
 - Drying, calcination (= formation of Cu₂O NPs on SiO₂), (reduction of Cu₂O to Cu NPs)
 - Solubility limits!

- Weak interaction = Impregnation methods
 - Dry impregnation (Incipient wetness impregnation)
 - Big issue: Gas trapped inside the pores

Pore collapse Mechanical degradation Attrition

• •

- Weak interaction = Impregnation methods
 - Dry impregnation (Incipient wetness impregnation)
 - Big issue: Gas trapped inside the pores

Possible solutions:

- No gas (impregnation under vacuum)
- Lower surface tension (addition of a surfactant)
- Wait until gas dissappears and impregnation is completed (either gas dissolves in solution or bubbles move out from the pores)

- Weak interaction = Impregnation methods
 - Dry impregnation (Incipient wetness impregnation)
 - Big issue: Gas trapped inside the pores

- Three types of interaction between support and active phase
 - Weak
 - Electrostatic
 - Covalent

- Electrostatic interaction = Ion exchange
 - Classic ion exchangers: clays, layered hydroxides,
 zeolites
 - Oxides with the help of pH

- Electrostatic interaction = Ion exchange
 - Zeolites, how does it work?

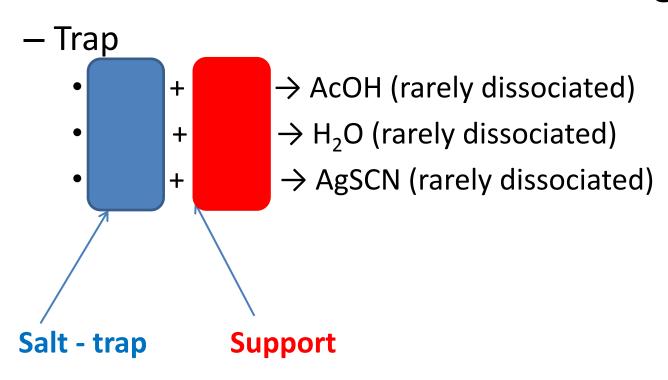

- Cation compensating the negative charge?
- Na⁺ from the synthetic step

- Electrostatic interaction = Ion exchange
 - Zeolites, how does it work?
 - $Na^+ \rightarrow H^+ directly?$
 - $\text{Na}^+ \rightarrow ??? \rightarrow \text{H}^+$

- Electrostatic interaction = Ion exchange
 - Zeolites, how does it work?
 - $-\operatorname{Na}^{+} \to \operatorname{NH}_{4}^{+} \stackrel{\operatorname{\Delta^{T}}}{\to} \operatorname{H}^{+}$
 - Zeolite NaY
 - Up to 73 % of Na⁺ can
 be exchanged at R.T.
 - 4 consecutive steps
 or
 continuous ion exch.

- Electrostatic interaction = Ion exchange
 - Enhancement...trap for leaving ion (shifting equilibrium)!
 - e.g. Exchange of Ni²⁺ for H⁺ in zeolite mordenite
 - $Ni(NO_3)_2 vs. Ni(OAc)_2$

Electrostatic interaction = Ion exchange

- Electrostatic interaction = Ion exchange

 - Oxides with the help of pH

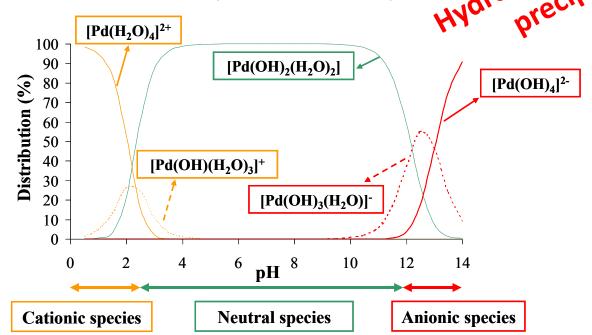

- Electrostatic interaction = Ion exchange
 - Oxides with the help of pH

- Electrostatic interaction = Ion exchange
 - Oxides with the help of pH
 - Isoelectric point

- Electrostatic interaction = Ion exchange
 - Oxides with the help of pH
 - Exchange capacity: the farther you are from isoelectric point, the higher the exchange capacity.

- Electrostatic interaction = Ion exchange
 - Oxides with the help of pH
 - Stability of support at different pH!

Precursor stability at different pH!

- Electrostatic interaction = Ion exchange
 - Oxides with the help of pH
 - Competitive ion exchange

- Example: very high affinity between Al₂O₃ and Pt
- Result: heterogeneous distribution of Pt (only outer surface)

- Electrostatic interaction = Ion exchange
 - Oxides with the help of pH
 - Competitive ion exchange

2-

- NH₄OH dissociates readily, NH₄⁺ competes with Pt for sites (= inverse to trap)
- Result: homogeneous distribution of Pt through the support

- Electrostatic interaction = Ion exchange
 - Oxides with the help of pH
 - Competitive ion exchange

- Electrostatic interaction = Ion exchange
 - Oxides with the help of pH
 - Competitive ion exchange

- Electrostatic interaction = Ion exchange
 - Oxides with the help of pH
 - Competitive ion exchange

- Electrostatic interaction = Ion exchange
 - Oxides with the help of pH
 - Competitive ion exchange: Note
 - We say homogeneous Pt distribution...
 - But how homogeneous???
 - Latest research from de Jong group (University Utrecht, HR-TEM, perfect control of Pt deposition on atomic scale) shows that uniform Pt homogeneity is not ideal for hexane isomerization!

- Electrostatic interaction = Ion exchange
 - Oxides with the help of pH
 - Detailed knowledge of isoelectric point, precursor behavior, control over pH:

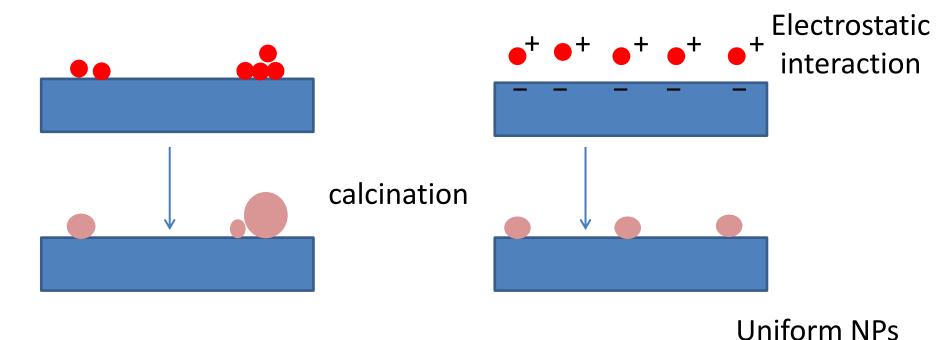

Synthesis of ultrasmall, homogeneously alloyed, bimetallic nanoparticles on silica supports

A. Wong, Q. Liu, S. Griffin, A. Nicholls, J. R. Regalbuto *

- Electrostatic interaction = Ion exchange
 - Oxides with the help of pH
 - Detailed knowledge of isoelectric point, precursor behavior, control over pH:

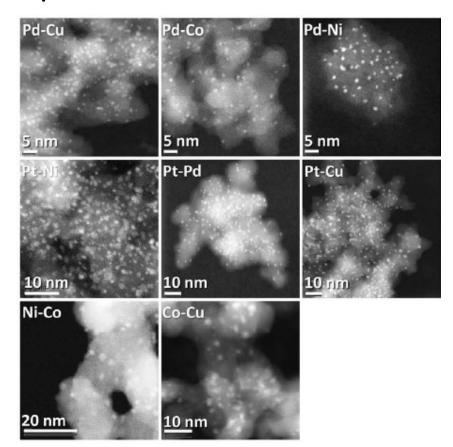

Supported nanoparticles containing more than one metal have a variety of applications in sensing, catalysis, and biomedicine. Common synthesis techniques for this type of material often result in large, unalloyed nanoparticles that lack the interactions between the two metals that give the particles their desired characteristics. We demonstrate a relatively simple, effective, generalizable method to produce highly dispersed, well-alloyed bimetallic nanoparticles. Ten permutations of noble and base metals (platinum, palladium, copper, nickel, and cobalt) were synthesized with average particle sizes from 0.9 to 1.4 nanometers, with tight size distributions. High-resolution imaging and x-ray analysis confirmed the homogeneity of alloying in these ultrasmall nanoparticles.

NPs by wet (dry) impregnation vs. impregnation with electrostatic interaction

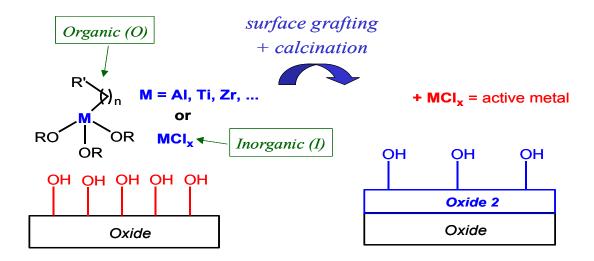

- Electrostatic interaction = Ion exchange
 - Oxides with the help of pH

We demonstrate a simple method that can be applied to noble and base metals alike to synthesize ultrasmall (~1 nm) NPs with homogeneous alloying. The method is based on strong electrostatic adsorption (SEA), whereby charged metal precursors are strongly adsorbed onto oppositely charged oxide or carbon surfaces by controlling the pH relative to the surface point of zero charge (PZC) (7-9). This interaction holds the precursors in place during drying, as opposed to IMP, in which the metal precursors remain and aggregate in solution as drying occurs. The required surface charge is provided by the native OH groups on the surfaces; no explicit surface functionalization is needed. This method involves fewer steps than colloidal methods of NP synthesis and eliminates the problematic removal of the capping agents of those methods, because no capping agent is used.

- Three types of interaction between support and active phase
 - Weak
 - Electrostatic
 - Covalent

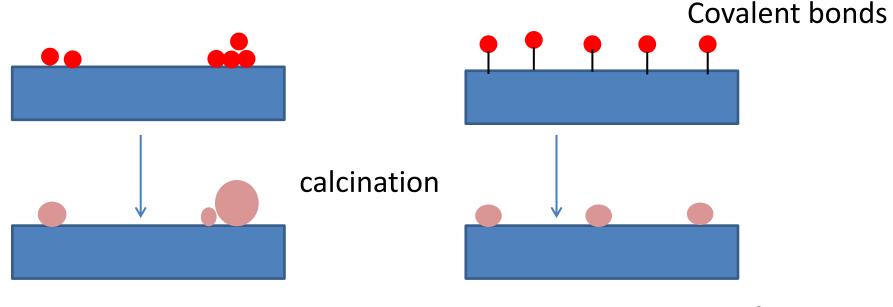

- Covalent bonds = grafting
 - Formation of metal oxide on top of catalyst support

 Is calcination necessary? More in lecture on single site catalysts...

- Covalent bonds = grafting
 - Formation of metal NPs on top of catalyst support

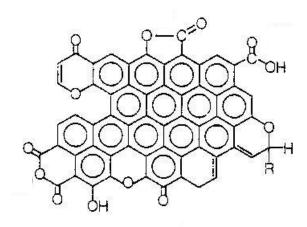

- Covalent bonds = grafting
 - NPs by impregnation vs. grafting

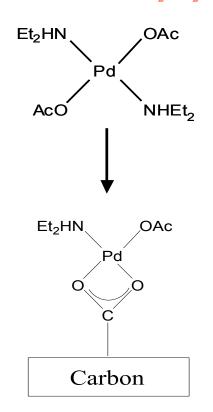

Uniform NPs

- Covalent bonds = grafting
 - Formation of metal NPs on top of graphene oxide

complex [Pd(OAc)₂(Et₂NH)₂]

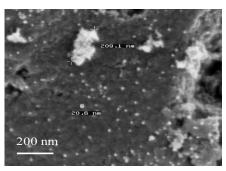

Content of COOH groups increased by oxidation $(HNO_3, H_2O_2, O_3, ...)$

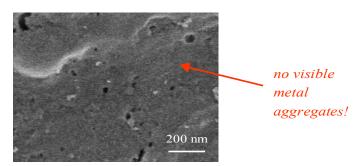

- Covalent bonds = grafting
 - Formation of metal NPs on top of graphene oxide
 - Last step: Pd reduction

Without
functionalization
by oxidation
(thus almost no
grafting)

With
functionalization
by oxidation
(thus grafted Pd
complexes)

- Covalent bonds = Deposition/precipitation
 - Starts as a dry impregnation
 - Metal salt is then selectively precipitated at the catalyst surface
 - Precipitation mainly by pH change –
 hydrolysis/condensation
