First of all, according to the authors, it is necessary to answer the question of the link between SEPA payment products and cross-border and domestic payment systems of individual EEA countries and Switzerland. Here it is necessary to realize whether the country belongs to euro zone or not. SEPA products are essentially binding for all countries, both for cross-border payments and domestic payments. This obligation arises from the above-mentioned Regulations No 260 or Regulation No 248. Countries outside the euro zone continue to access the project through their providers on a voluntary basis and conclude the Adherence Agreement to the EPC.

Table 1 shows the number of participants between 2010 – 2017, which are providers of SCT and SDD.

**Table 1: Numbers of Participants Involved in SEPA Products**

Product/year	2010	2011	2012	2014	2015	2016	2017
<b>SCT</b>	4471	5841	5883	4512	4474	4437	4163
<b>SDD – core</b>	3236	4049	4047	3902	3742	3696	3415
<b>SDD – B2B</b>	2817	3380	3380	3412	3355	3303	2998

Source: EPC, own elaboration (2011-2018)

Author's note: the authors don't have data for 2013

From this overview, it is clear that the number of members using SEPA instruments has been declining since 2014. This trend can be attributed to both the fact that the EPC lists are referenced only providers - banks with assigned BIC (Business Identifier Code) and, secondly, a partial reduction in the number of providers of these products due to e.g. merger.

New scheme EPC, which is SCT<sub>inst</sub>, (SEPA Credit Transfer Instant Payments) officially launched in November 2017 – enables euro credit transfers with the funds made available on the account in less than ten seconds at any time and in an area that will progressively span over 34 European countries. To add to this, SCT<sub>inst</sub> already has 1,044 participants (EPC, 2018) on February 9, 2018.

However, the criterion, which better outlines the significance of the SEPA project (and thus its core instruments - SCT and SDD) for European integration in the payment system, is the analysis of its shares of the numbers and volumes of these transactions in the total settlement of payments in EURO. Numeric and graphical expressions are shown in Figure 1 and Figure 2. The STEP2 and / STEP1 / EURO1 processes exclusively SEPA payments, other payment systems then other euro payments that do not meet the SEPA criteria. (Note: Target, STEP1/EURO1, CLS a STEP2 are the main EEA clearing systems).

**Figure 1: Share of European Payment Systems in % - Number of Transactions**

Source: European Central Bank. Payment statistics, February, 2018. Available at: <http://sdw.ecb.europa.eu/reports.do?node=100000760>; own elaboration (2017)

**Figure 2: Share of European Payment Systems in % - Transaction Volumes**

Source: European Central Bank. Payment statistics, February, 2018. Available at: <http://sdw.ecb.europa.eu/reports.do?node=100000760>; own elaboration (2017)

From the above values we can state two partial conclusions:

1. In terms of the number of payments (Figure 1), SEPA products are clearly decisive as the STEP2 system has a share of up to 98.4% (2016) on all interbank euro payments of the EEA countries. Since 2011, the share of SEPA payments has been steadily increasing, due to EMU countries being obliged to process both cross-border and national SEPA-based transfers.
2. However, the TARGET settlement system is absolutely dominated by the volume of payments. Its dominance can be explained by the fact that it balances the positions of banks, especially EMU countries, against the ECB. STEP2 is only 2.1% (2016), but SEPA has grown 10 times over the period under review.

#### 4. Conclusion

In the author's opinion, SEPA can be considered very important as it unifies the national and cross-border payments of EMU countries and facilitates the standardization of transfers of payments in cross-border euro transfers in other EEA countries.

SEPA is a key player in the EMU, but not in the other EEA countries. This is due to the fact that in EMU countries the SEPA providers are required to comply with the standard, which is given by European regulation. In terms of the share in the number of operations, SEPA is a key tool in promoting European integration by using bank clients in SEPA products in accordance with established rules. However, in terms of the volume of transactions, SEPA does not play a significant role. In this criterion, SEPA is relatively insignificant. In addition, the number of SEPA providers based on SCT and SDD has been decreasing since 2014.

### **Abstract**

*The topic of housing situation in Poland in 2014-2018 represents a very serious problem which remains to be very topical. The aim of the study was to present the housing situation in Poland compared to the current situation in the EU. It was proposed that the implementation of a new government program within the economic policy of the country should have an insignificant positive effect on the improvement in housing situation in Poland. The results of the empirical research conducted by research institutions in Poland and the EU concerning the housing market presented in reports published by Forsal, Newsweek, OECD, Eurostat, Deloitte and GUS were used to achieve the study aim. The study also presents the structure of residential housing, the sector of houses and flats for rent and the price structure of newly built flats compared to the housing situation in the EU. The analysis supported the thesis of a positive effect of government programmes on the improvement in housing situation and, consequently the positive effect on the economic development of the country.*

**Keywords:** *housing in the EU, Mieszkanie Plus program, ownership structure in housing, price structure*

**JEL Classification:** *E64, G28, R21, R31, R38*

### **1. Introduction**

A comfortable flat at a reasonable price in safe location is the basic need and a fundamental right of each human. Facing the problems of poverty and social inclusion, meeting this need represents a substantial challenge to many European countries (Stephens and Leishman, 2017). According to the status as of 31 December 2016, housing resources in the country accounted for 14.3 million flats with total usable floor area of 1,053.3 million square metres, with 54.6 million rooms (GUS<sub>2</sub> [online], 2017, pp. 18, 27). The owners of most flats were natural persons, with 8.2 million apart from housing associations (57.5%) and nearly 2.9 million (20.5%) in housing associations. Total floor area of flats owned by natural persons was over 900 million square metres, accounting for nearly 86% of total floor area of flats in Poland. Resources of housing cooperatives were nearly 2.1 million flats with total floor area of 102.3 million square metres. The lowest number of flats were those owned by the State Treasury: ca. 29.1 thousand flats with total floor area of nearly 1.5 million square metres (Leszczyński and Olszewski, 2017).

According to official data of the Central Statistical Office for the year 2013 in Poland, there were 364 flats per 1,000 people, whereas the EU's mean was over 420 flats in 2011. In France, this index was 538, in Denmark - 497, and in Germany - 493. The data of the most recent census (2011) showed that the statistical deficit of flats was slightly over one million. The

scope of activities in the residential construction sector is insufficient. In 2014, there were only 760 new flats per 1,000 new married couples (Forsal [online], 2017).

Furthermore, housing needs and lifestyles of young Poles change substantially to the benefit of the sector of houses and flats for rent. The need for having the property is being gradually ousted by mobility and financial liquidity. Although operating quite effectively, the private sector of houses or flats for rent:

- is relatively small and focused on large cities,
- most of residential units for rent in the Polish market are owned by private individual investors while the sector is fragmented;
- privatization caused large differentiation of the property structure in most of residential buildings in Poland.

These facts are not conducive to standardization of the principles of rent, sense of safety of the tenants and improvement in the housing situation in Poland.

With respect to housing, governments implement rather individual policies. Most of the EU member states, however, are facing similar challenges, for example: how to recover housing resources, how to plan the development of cities and combat their uncontrolled growth, how to support sustainable development, how to help young people and groups with unfavourable financial status in the market and how to promote energy efficiency among owners of houses and flats. The problems of housing play a significant role in the social agenda of the EU (Eurostat [online], 2017). The aim of the study was to present the housing situation in Poland compared to the current situation in the EU. It was proposed that the implementation of a new government program within the economic policy of the country should have an insignificant positive effect on the improvement in housing situation in Poland.

## 2. Assumptions of the Mieszkanie Plus Government Programme

The program Mieszkanie Plus ("Flat Plus") government programme represents a response to unsatisfied needs in the housing market. As results from the examinations, nearly half of Poles are excluded from this market, including those professionally active and part of medium class. Over a million of Polish families cannot afford to buy or rent a flat and have to share it with other household members. The challenges are posed not only by high prices of flats but also by insignificant floor area per person and a relatively low standard of housing units. It should be clearly stated that without changes in this status, no breakthrough can be expected in the dramatic demographic situation in Poland.

The aim of the primary version of the programme was to promote cheap construction for rent and providing Poles with access to flats for rent at preferential prices and renting flats with the option to purchase them in the future. The program was signed on 27 September 2016, whereas its implementation started in the fourth quarter 2017. As assumed by the government, with the implementation of the program, the number of flats per 1,000 people is supposed to rise to 435 (according to GUS, in 2016, when the program was adopted, this number was 363) (Bankier [online], 2016).

The main pillar of the new program was the establishment of the National Housing Fund, supported with the land owned by the State Treasury. Consequently, the flats built on this land will be cheaper. Essentially, these will be flats for rent, with initial assumption of the option of taking over the property rights in the future and predicted rent of **from 10 to 20 PLN per square metre**. The preferred beneficiaries will be large families.

Another important component of the new program is **social support of the sector of construction of flats for rent and the cooperative construction sector**. Local governments

that implement investments in housing units with low rents and protected flats, municipal flats and shelters and night shelters for the homeless will be able to obtain from 35 to 55% of funding. Housing cooperatives, social building associations and developers will be also eligible for funding of construction of flats for rent. Furthermore, the program intends to implement 20% funding for gminas involved in construction with investors and preferential loans available in BGK bank (for gminas, housing cooperatives and social building associations).

The third element of the new programme is to create individual super accounts in banks, termed Individual Housing Accounts (Indywidualne Konto Mieszkaniowe, IKM), **which represent the support for people saving money from 2019, i.e. after completion of the previous MDM programme. During the session on 21 February 2018 the government adopted that IKMs can be set up in any bank, but they will be supervised by the Bank Gospodarstwa Krajowego (BGK).** The first IKMs should be offered by banks in 2018, whereas the saving bonuses will be paid from 2019. The government did not make a decision on the maximal level of savings on IKMs for which the bonuses will be paid and the maximal levels of the bonuses.

The allowances for IKMs will be supported by the budgetary resources from the specific reserves. The minimal period of saving is 5 years. **The funds collected in IKMs can be spent on any housing purposes:** renovation of flats, purchase of a flat, deposit in the housing cooperative, building a house or deposits in social building associations. If the resources are not used for housing purposes, the owner will be obliged to return the bonus to the bank where the account was set up.

The National Housing Program will be supervised by the National Housing Council as a counselling and assessment entity established in the office of the Prime Minister of the Republic of Poland. The members of the council include experts from the sector of real estate and finance, whose tasks will be annual assessment of the activities started within the program (Business Insider [online], 2018).

The new Mieszkanie Plus government programme, based on construction of flats for rent at preferential prices and renting flats with the option to purchase the flat is supposed to provide people with their own flats, thus improving the housing situation in Poland.

### 3. Problem Formulation and Methodology

The motivation for starting the analysis of housing situation in Poland was unsatisfied housing needs of Poles. The aim of the study was to present the data about housing situation in Poland in 2014-2016 compared to the situation in the EU. It was proposed that the implementation of a new government program within the economic policy of the country should have an insignificant positive effect on the improvement in housing situation in Poland. The study used available literature concerning the real estate sector and the results of empirical examinations performed by national and foreign research institutions.

The aim was achieved by using the data contained in the reports prepared by Forsal, Newsweek - OECD, Eurostat, Dolittle and GUS using the method of secondary data analysis. The data allowed for presentation of the property structure in the housing sector and price structure of newly built flats. The structures of the housing sector of houses and flats for rent and privately-owned housing sector were also presented. Presentation of the residential housing sector was compared to the current housing situation in the EU.

The analysis was performed to achieve the study aim and support the adopted hypothesis.

#### 4. Problem Solution

A very large deficit of flats in Poland does not fully satisfy the housing needs, which are substantial (Newsweek [online], 2015). In the case of young Poles, the housing needs and preferred lifestyles are changing towards renting flats that allows for mobility, flexibility and financial liquidity and the decreasing need for ownership. Recently, after years of a decline, the private sector of flats for rent in large cities has increased substantially and became an alternative to many Polish households (Deloitte [online], 2017). Since the private rental sector has little effect on the national market, the main method to invest in real estate for rent in Poland is to implement developmental projects. The interest in projects that promote housing for rent is increasing.

The condition of housing in Poland reflected by housing resources and values of indices that reflect the mean number of rooms in a flat, number of people per flat and per room and usable floor area per person is presented in Table 1 and 2.

**Table 1: Housing Resources in Poland According to Forms of Property (2016)**

Specification	Flats	Floor area, m <sup>2</sup>
<b>TOTAL</b>	14,272,010	1,053,251,803
<b>Property:</b>		
<b>Housing cooperatives</b>	2,073,935	102,336,104
<b>Gminas (municipal)</b>	868,517	38,306,151
<b>Company</b>	79,308	4,564,658
<b>State Treasury</b>	29,127	1,473,620
<b>Social building associations</b>	98,221	4,843,218
<b>Natural persons:</b>		
<b>In housing associations</b>	2,896,622	151,532,068
<b>Apart from associations</b>	8,200,535	748,761,778

Source: GUS<sub>a</sub> (2017, pp. 328-333), GUS<sub>b</sub> (2017, pp. 18-19)

**Table 2: Housing Conditions in Poland in 2005 - 2016**

Mean indices of:	2005	2010	2015	2016
<b>Number of rooms per flat</b>	3.69	3.81	3.82	3.82
<b>Number of people per flat</b>	2.99	2.86	2.72	2.69
<b>Number of people per room</b>	0.81	0.75	0.71	0.70
<b>Usable floor area per person [m<sup>2</sup>]</b>	23.2	25.3	27.0	27.4

Source: Uchwała (2016), GUS<sub>a</sub> (2017), GUS<sub>b</sub> (2017)

Table 1 shows that there were 6071,5 thousand flats in 2016 in buildings which were subjected to management/administration. Among them, 47.7% were flats of natural persons in buildings included in housing associations, 34.2% were property of housing cooperatives, 14.3% - municipal flats, 1.6% - social building associations, 1.3% - company flats, 0.5% - the State Treasury, and 0.4% - flats owned by other entities. These data clearly point to the fact that contribution of a cheap flats in social building associations (TBS), in both cooperative and municipal housing, accounts for ca. 50% of flats in buildings under management or administration and 20% of housing resources (Sitek, 2016). Their contribution to promotion

of cheap construction is rather insignificant, leading to the necessity of using effective development projects.

Analysis of housing conditions in Poland in 2005-2016 (Table 2) indicates the substantial increase in the number of flats, rooms in a flat and reduction in the number of persons per room. This tendency was caused, among other things, by new investments in housing, extension and reconstruction of current buildings and changes in the character and purpose of non-housing floor areas. Comparison of mean costs of purchase and rent in 2016 in selected European countries is presented in Table 3.

**Table 3: Mean Costs of Purchase and Rent of Flats in Selected European Countries (2016)**

Country	Mean price per square metre of a flat	Mean monthly cost of rental per square metre of a flat
Austria	3443 EUR	9.5 EUR
France	5440 EUR	21.0 EUR
Germany	3700 EUR	10.0 EUR
Poland	1299 EUR	7.5 EUR
Romania	1150 EUR	5.5 EUR
Switzerland	7541 EUR	17.8 EUR

Source: based on: Eurostat (2017), Deloitte (2017), Forsal (2017)

As shown in Table 3, mean price per square metre of a flat is 2200-2600 EUR, with large differences between countries (Romania: 1150 EUR/m<sup>2</sup>, Switzerland – 7541 EUR/m<sup>2</sup>) (Barrios and Javier, 2017). Also the prices of rental are characterized by high variation. Relatively low costs of rental in Germany and Austria compared to mean prices per square metre of a flat in these countries were 0.27% (Wind et al. 2017). This reflects an efficiently functioning market of flats for rent. In Poland, the price per square metre of a flat is at the level below the EU's average at a relatively low rental price. Relation of these prices is twice higher than in Germany and Austria (0.58%). This high ratio of the rental price to price of a square metre of a flat suggests a poorly developed market of houses and flats for rent in Poland and its huge developmental potential.

**Table 4: Flats for Sale and Rent in the Housing Resources in 2010, 2015, 2016**

Specification	2010	%	2015	%	2016	%
<b>Average usable floor area per 1 flat [m<sup>2</sup>]</b>	106.1		99.8		96.4	
<b>For sale and rent</b>	66.2		58.5		58.2	
<b>Flats delivered to the market in thousands</b>	135.8	100	147.7	100	163.3	100
<b>For sale and rent</b>	53.3	39.3	62.4	42.2	79.2	48.5
<b>Flats per 1,000 new married couples</b>	595	100	782	100	844	100
<b>For sale and rent</b>	158.6	26.7	173.5	22.2	220.9	26.2
<b>Usable floor areas of flats in thousands square metres</b>	14441	100	14739	100	15427	100
<b>Floor area of a flat for sale and rent</b>	3544	24.5	3654	24.8	4607	30.0

Source: GUS<sub>a</sub> (2017, pp. 332-333)

In 2000, the most prevalent form of state's intervention concerning the improvement in housing situation in the country was to offer flats for rent by the National Housing Fund that operated at the BGK bank. Furthermore, with the private sector of real estate, rent started to be important as an alternative to many households, but this tendency was incomparable to European standards. The figures for flats delivered in 2010, 2015 and 2016, with specification of flats for sale and flats for rent are presented in Table 4.

All the indices in Table 4 that characterize housing resources suggest the improvement in housing conditions in the population. However, they remain to be substantially lower than in the developed countries of the EU. This conclusion is also reflected by the housing statistics for Poland and the EU (Uchwała [online], 2016, pp. 9-10 and Eurostat [online], 2017), presented in Table 5.

**Table 5: Statistical Data for Housing of Poland and EU (2016)** (% of the population)

<b>EU 28</b>	16.7	29.5	5.0	4.9	11.3	6.7	6.8	27.0	12.4

Source: Eurostat (2017)

The data presented in Table 5 were derived from the European survey of incomes and conditions of living in the EU 28 countries (Eurostat [online], 2017, and Barrios and Javier, 2017). The data show that Poland, compared to the EU, has to face numerous challenges, with substantial housing needs in terms of types and legal titles to flats, overpopulation, housing deprivation and overload with housing expenses. The statistics reveal (Uchwała [online], 2016), that of 27 of the EU countries, Poland is 19th in terms of average size of the flat, 24th in terms of the usable floor area per person and 23rd in terms of overpopulation index. Furthermore, mean prices of new flats in the EU and Poland are as follows: maximal value of the transaction price is 14089 EUR/m<sup>2</sup> for the London's centre, 7980 EUR/m<sup>2</sup> in the London's outskirts, 10266 EUR/m<sup>2</sup> in Paris, 6500 EUR/m<sup>2</sup> in Tel Aviv, whereas the lowest level was found for Porto: 860 Eur/m<sup>2</sup>. In Poland, these levels were 1101 EUR/m<sup>2</sup> in 2013 and 1111 EUR/m<sup>2</sup> in 2014. This analysis emphasizes an unfavourable housing situation of Poland compared to the EU countries.

Housing situation in Poland leads especially to emigration of young Poles. Furthermore, with the inflow of immigrants from Ukraine caused by socio-political situation of this country, the need for flats for rent are increasing. The deficiencies in labour force in Poland, caused by economic emigration of young people to the EU countries, also lead to opening of the labour market while increasing the demand for flats for rent. Consequently, the prices of flats and

rents are increasing. Therefore, the housing situation in Poland compared to the developed countries of the EU should be considered as unfavourable. The analysis showed unequivocally that the labour market in Poland requires a strong support, especially in the area of flats for rent. Since the sector of rent of privately-owned flats, despite the recent substantial growth, is insignificant to the national market, the improvements in the housing situation can be expected to be stimulated by governmental development projects as major methods of investing in real estate for rent.

The statistics concerning housing presented in this study and the property and price structures of the housing for Poland in the context of the EU show that there is much space for the improvement in terms of housing in order to reach average European standards. This is the responsibility of the government, which, using the *Mieszkanie Plus* program, with all its availability and benefits, assumes a substantial improvement in the housing situation while developing its own policy. In the context of the housing situation presented in the study, the government made the decision on the implementation of the *Mieszkanie Plus* programme in order to improve this situation.

## **5. Conclusion**

Previous housing policy failed to respond to the basic challenges connected with availability of flats for households with average and low incomes. With the main aim to support the housing sector in Poland, the recently implemented *Mieszkanie Plus* government programme is expected to improve this situation.

The analysis carried out in the study led to confirmation that the share of cheap housing construction is not sufficient to satisfy housing needs in the country, and that the large housing deficit places Poland well below European standards. In Poland, the current housing situation affects, in part, the economic emigration of young people to the EU, but the *Mieszkanie Plus* program based on renting is to guarantee a flat for life. The implementation of this guarantee already in the very assumption of improving the housing situation and at the same time only slightly supporting the rental market, shapes domestic policy in this field. In the proposed programme promoting large families will make young people queue up waiting for long years, and beneficiaries of the program will not be able to choose the type of property, location and standard. However, in the case of rental, the increased demand for rental apartments in the near term must result in an increase in rental prices, not conducive to improving the housing situation in Poland.

Furthermore, analysis of housing situation in Poland showed that despite continuous improvement in housing situation in Poland, basic indices of housing resources and conditions remain to be much lower than in the developed countries of the EU. The private sector of houses or flats for rent in Poland, although operating relatively efficiently, is relatively small, focuses on larger cities and has no capabilities to improve housing situation in the country. Despite ambitious objectives and quite a long perspective, the *Mieszkanie Plus* government programme, is likely to support current housing situation; however, due to its drawbacks, the scale of support may be not substantial.

The analysis of the housing situation in Poland compared to the EU countries allowed for the achievement of the study aim, and led to the conclusion that the effect of the *Mieszkanie Plus* government programme on the improvement in the housing situation is limited.

Further research is planned to assess the impact of government policy implementation on the improvement of the housing situation in Poland.

## **Abstract**

*Sustainable energy development is a process of permanent, safe and effective energy supply for the needs of sustainable development. The competitiveness of countries is directly related to the progress achieved in implementing sustainable energy development as the energy sector has great significance for the future development of the country, for economic growth and has a major impact on the environment. The aim of the article is to present the concept of sustainable energy development and indicators for assessing the development of energy in the following dimensions: social, economic and ecological. An attempt was made to assess the sustainable energy development in Poland against selected European Union countries. The following indicators of sustainable energy development were compared: sustainable consumption and production, marking the production and consumption of energy; climate change, marking GHG emissions and the share of renewable energy in gross final energy consumption; sustainable transport, marking the energy consumption of transport relative to GDP.*

**Keywords:** *alternative energy source, energy indicators, energy sector, sustainable energy development*

**JEL Classification:** *F64, O13, Q42*

## **1. Introduction**

Difficult access to energy resources and the environmental degradation are some of the basic threats to economic development of the contemporary world. In these circumstances the concept of sustainable development is more than just a theoretical solution and becomes an actual tool for shaping human development. The application of the concept necessitates its description for individual sectors of the economy. One of the key areas for sustainable development is power industry. Many countries create new concepts of its development and modify their energy systems to be compatible with the goals of sustainable development. Due to high costs, the strategy of sustainable development based on climate sustainability which is part of the "Europe 2020" document and the European Union's objectives for 2030 and beyond is a major challenge for many countries (Štreimikienė, Ališauskaitė-Šeškienė, 2016, p. 4-18). The reason for this in Poland is the one-sided structure of energy balance and the very nature of the Polish energy system which implies this structure. The winter package, a document called "Clean Energy for all Europeans", which was published by the European Commission on 30 November 2016, introduces admissibility of electric energy sources with CO<sub>2</sub> emission level below 550 kg/MWh on the power market. It thus eliminates all coal power plants and prevents the Member States from choosing their energy mix freely. Additional restrictions are brought by new regulations in the European Union based on BAT techniques. They tighten the

limits of the emission of nitrogen oxides, sulphur oxides and dust particles which so far have been regulated by the directive on industrial emissions from sources above 50MW, and introduce limits on chlorine compounds and heavy metals. The implementation of new regulations, which embrace also medium size sources (1-50MW), means significant expenditure on the adaptation of commercial and industry energy sources and heating. That is why the realization of the requirements of the European Union's climate and energy policy is a major and difficult problem for Poland. (Włodarczyk, 2016, p.1086-1095)

The goal of the article is to explain the notion of the "sustainable development of the energy sector." The paper discusses indicators which describe it in the social, economic and ecological dimensions. An attempt was made to assess the development of sustainable energy in Poland and selected European Union countries.

## 2. Comparative Study of the Notion of Sustainable Energy Industry

Sustainable development is the basic and primary goal of the European Union (Article 3 on the Treaty of the UE [online], 2018). The definitions of sustainable development indicate the need for the integration of development goals: economic, ecological and social. New Agenda for Sustainable Development 2030 covers 17 goals, among which goal 7 is key - to secure access to low-cost, sustainable energy to everyone. Energy policy of the European Union regarding the electricity sector, according to the provisions of the Green Paper from March 2006 (COM, 2006,0105), aims at the realization of tasks along the philosophy and principles of sustainable development. The subject literature gives a few definitions of the sustainable development of energy. They refer to the definition of sustainable development presented by the Brundtland Commission (Our Common Future [online], 1987). W. Patterson defines the sustainable development of energy as: "the use and supply of energy which meet our needs without putting the ability of our children to satisfy their needs at risk" (Patterson, 2009, p.14). Lemaire's view is similar (Lemaire, 2004) and J.W. Tester et al. (Tester et al., 2005, p.XIX) focus mainly on the problem of sustainability. Long-term accessibility, as the central interest of the concept of sustainable development, should be offered in accordance with the environmental protection requirements. The third area is the social aspect. It is not as emphasized as environmental matters, but is also present in the definitions of sustainable energy W. Tester and UNDP (Tester et al., 2005, p.XIX; UNDP, 2000). A broader socio-economic and economic approach towards sustainable energy is also present in the definition by Citizens Network for Sustainable Development (Prandecki, 2014, p.240). Also the LG Action organization, which concentrates local governments acting in favor of sustainable development, points out that sustainable energy is not just a problem of sustainability. It is also connected with the authorization for use of energy sources whose production and utilization does not have a negative influence (or it is just slight) on people's health, the environment and the functioning of natural systems. (LG Action, [online], 2009). The policy of sustainable energy in three dimensions: ecological, economic and socio-cultural is also described by H. Rogall (Rogall, 2009). In his research he proposes three criteria of sustainable development: ecological dimension (global warming, natural tolerance, the consumption of non-renewable resources, excessive use of renewable resources, hazards for human health), economic dimension (influence on the state economy, meeting energy needs, short-term security of supply, good prices), socio-cultural dimension (social tolerance, constant security of supply, integration with existing infrastructure, avoiding participation in global conflicts, security). A division of sustainable energy into three pillars is also presented by G. P. Hammond i C.I. Jones (Hammond and Jones, 2011). According to the quoted authors, in the framework of the environmental pillar the effects of the application of a given technology should be subject to environmental impact assessment. Life cycles and full fuel cycles could serve as tools for such

an analysis. In the area of the economic pillar we carry out an analysis of costs and benefits for the environment. The social pillar focuses on an ethical assessment of the influence of existing and potential energy sources on the environment and society. The subject literature highlights the importance of the entire sustainable energy system which meets the requirements of the concept of sustainable development. It also emphasizes that efficient energy management is just as significant as its efficient production (Mitchel, 2010, p.9). An interesting definition of sustainable energy industry is offered by K. Prandecki (Prandecki, 2014, p.240). He defined it as a change of primary energy into electric energy and heat provided to the end user in a way which ensures satisfying the needs of current and future generations with the consideration of economic, social and environmental aspects of human development. The dynamics of the process of sustainable development was underlined by A. Graczyk (Graczyk, 2017, p.53-68). He defines the sustainable development of the energy sector as a process of sustainable, secure and effective energy supply. Put in this way, sustainability means ensuring access to energy with the principle of intergenerational fairness. Sustainability of development is a balance between its three dimensions: social, economic and ecological.

### **3. Indicators of the Sustainable Development of the Energy Industry**

Sustainable development of energy industry, which is a crucial element of sustainable development, is monitored with a set of various indicators in international comparisons as well as on the European level with the purpose to evaluate the goals of energy, climate and ecological policy (Sahabmanesh, Aref, Saboohi, Yadollah, 2017, p.66-79). The measures of sustainable development enable a statistical presentation of a country from the point of view of the implementation of a new development paradigm. Their most important feature is comparability which facilitates the determination of the position of a given object, such as a country, with reference to other objects. The set of indicators of the sustainable development of the EU consists of many thematic areas, from economic, social and ecological to the institutional dimension and global partnership. They can be in the form of goals or structures which serve as reference models to be reached by sustainable development. Reaching these goals, or these positive target states in a given time is registered by the indicators of sustainable development.

#### **3.1 IAEA Indicators**

The IAEA set of variables monitoring the development of the energy industry is versatile. It works with different types of countries and energy systems and can also be used in a regional context. It approaches the problem of the sustainable development of energy comprehensively and excludes institutional indicators. The set consists of 30 indicators divided into three dimensions (social, economic and ecological) (Energy indicators, [online], 2005). The indicators are grouped thematically. Some of them can be classified in more than one dimension depending on the discussed issue.

#### **3.2 Eurostat Indicators**

The Eurostat database features a broad list of sustainable development indicators divided into ten thematic areas (Sustainable Development Indicators, [online], 2017). „Climate change and energy” is one of them and the following indicators were distinguished here: greenhouse gases emissions, primary energy use, energy saving, greenhouse gases emission according to sectors, energy dependence, share of renewable energy in the gross final consumption of energy, gross consumption of energy in a country according to fuel type, electric energy from renewable

sources, share of renewable energy in the fuel consumption in transport, combined generation of heat and energy, use of energy in transport in relation to GDP, energy tax rate (Sustainable Development Indicators, [online],2017).

### ***3.3 Indicators Monitoring the Achievement of the Goals of the Sustainable Development of Energy Industry by Central Statistical Office***

The elaboration by Central Statistical Office on the indicators of sustainable development contains a list of indicators of sustainable development arranged according to social, economic, ecological and institutional and political governances (Sustainable Development Indicators, [online], 2015).

Within individual governances there are also indicators connected with the power industry.

1. In the social governance area we find:
  - a) exposure of urban dwellers to excessive influence of PM10 dust;
  - b) exposure of urban dwellers to air contaminated with ozone;
  - c) consumption of energy in households per capita;
  - d) structure of average monthly expenditure per a household inhabitant per type (including household exploitation and energy carriers).
2. The ecological governance area contains:
  - a) greenhouse gases emission expressed in CO<sub>2</sub> equivalent;
  - b) emission of greenhouse gases across sectors;
  - c) emission of greenhouse gases per a unit of used energy;
  - d) quality of air (46 zones in a country where the quality of air is tested);
  - e) emission of acidifying pollution per 1 km<sup>2</sup>;
  - f) share of energy from renewable sources in the gross final consumption of energy;
  - g) share of energy from renewable sources in fuel consumption in transport;
  - h) percentage of expenditure on fixed assets for nonconventional sources of energy;
  - i) energy intensity of the economy.
3. In the economic governance area:
  - a) energy intensity of transport in relation to GDP.

The indicators used by Central Statistical Office largely overlap with the Eurostat indicators. Their diversity enables the monitoring of the development of sustainable power industry. The use of a set of indicators which comprehensively present the development of the energy industry can contribute to the determination of this development in a more balanced way.

## **4. Indicators of the Sustainable Energy Development in Selected EU Countries**

In order to analyze the sustainable development of energy in selected EU countries, the values of indicators leading in the following thematic areas were examined: sustainable consumption and production (electricity consumption in households per capita), climate change and energy (GHG emissions in CO<sub>2</sub> equivalent, share of renewable energy in gross final energy consumption), organization of transport respecting the principle of sustainable development (energy consumption of transport relative to GDP).

Transport is the key sector in the analysis of sustainable development. The energy consumption in transport indicator relative to GDP determines a percentage change in the final consumption of energy by transport per a GDP unit relative to 2010. A decrease in the indicator's value is a desired tendency. The indicator offers a possibility to determine the relation between energy

consumption in transport and economic growth. GDP increase should not be a consequence of an increase in the consumption of energy in transport. Since 2004 the majority of the countries have been reducing the final energy consumption in transport per a GDP unit. Some of the countries, though, saw an increase in 2015 compared to 2010: Bulgaria 110,1% and Croatia 104,3%. The other countries experienced a decrease. The average for the European Union was 93,4%. The lowest values among the analyzed countries were obtained in Ireland 71,6%, Poland 83,9% and Estonia 84,1%.

One of the main indicators for monitoring sustainable consumption and production of energy is the electric energy consumption in households per capita. It paints the picture of the consumption of electric energy by household inhabitants in time. A decrease in the indicator's value is a desired tendency. The increase of the indicator caused by lifestyle change (for example more electric appliances in a household) fosters "nonsustainable tendencies" in the consumption of energy by households which bring serious environmental impact.

**Figure 1: Electricity Consumption in Households per Capita (Total GJ)**

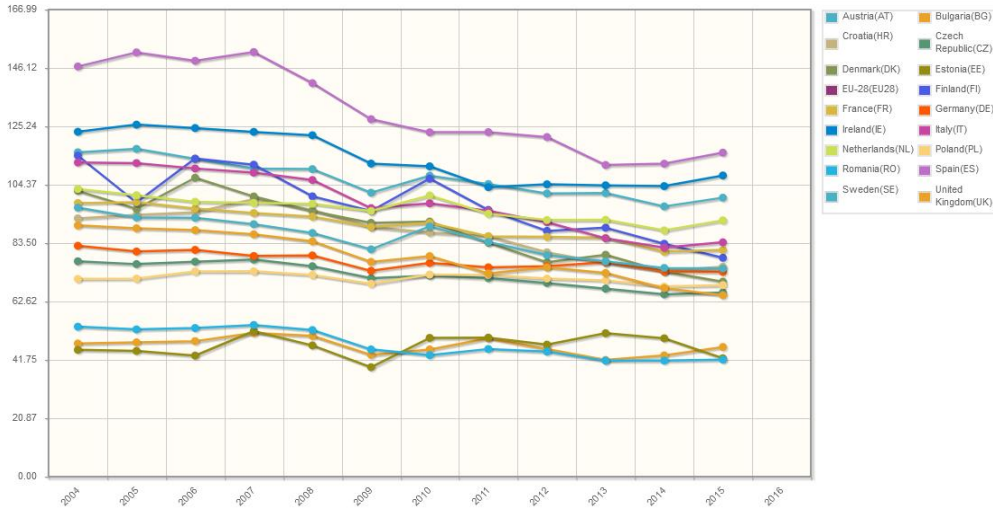

Source: own elaboration based on Eurostat (2018)

In 2015 the average electric energy consumption in households per capita in the UE-28 countries was 5,6GJ. The lowest value of the indicator, like in previous years, was observed for Romania 2,2 GJ and Poland 2,7 GJ. Among the countries with the highest indicator of electric energy consumption per capita (over 3 times higher than the Union average of 5,6 GJ), the following ones stand out: Sweden 15,8 GJ, Finland 13,7 GJ and France 13,7 GJ.

The indicators leading in monitoring the changes in climate and energy are GHG Emissions in CO<sub>2</sub> equivalent and the share of renewable energy in gross final energy consumption. The former determines the total annual emission of greenhouse gases created by men ("Kyoto Basket") in relation to the emission of greenhouse gases in the base year 1988 in accordance with the Kyoto Protocol, with the exclusion of emission from international air and sea transport and emission connected with land use and land use change and forestry (LULUCF). 1988 is the base year for Poland for the evaluation of the country's fulfillment of obligations of the Conference of the Parties of the United Nations Framework Convention (UNFCCC) and the

Kyoto Protocol. For the majority of countries the year 1990 was assumed. The base year for Poland for industrial gases (HFCs, PFCs, SF<sub>6</sub>) is 1995. The desired direction of change is the decrease in the indicator's value.

**Figure 2: GHG Emissions in CO<sub>2</sub> Equivalent (1988 =100); Total (%).Chart of Values for Years and for Separate Territorial Units**

Source: own elaboration based on Eurostat (2018)

Most EU countries record a drop in the total emission of greenhouse gases in relation to the base year which means they fulfill their obligation to reduce greenhouse gases emission to support sustainable development. In the group of the analyzed countries, the lowest emission in 2015 compared to the base year was observed in: Romania 41,85%, Estonia 42,33%, Bulgaria 46,33%. The highest in: Spain 115,84% and Ireland 107,68%. The obligation to reduce the emission of greenhouse gases in the first period of Kyoto Protocol (2008-2012) was fulfilled by Poland with a surplus as the country's greenhouse gases emission was reduced by 29,1%. Yet in order to protect the climate, further reductions of emission are necessary. In 2015 the emission level was 68,48%. It is estimated that a long-term quantitative goal is to reach a 30-40% reduction of greenhouse gases emission until 2020 in relation to the base year.

Another indicator in the area of tracking of climate and energy changes is the share of energy from renewable sources in gross final energy consumption. It reflects the level of energy from RES in the final energy consumption in a country. It provides monitoring of the effects of activities promoting the production and consumption of renewable energy in all sectors. Increasing pollution of the environment, growing energy demand and the exploitation of its traditional resources increment the demand for energy from renewable, environmentally friendly sources.

**Figure 3: Share of Energy from Renewable Sources in Gross Final Energy Consumption; Total (%). Chart of Values for Years and for Separate Territorial Units**

Source: own elaboration based on Eurostat (2018)

Since 2004 the countries have been increasing their share of renewable energy. In the analyzed group of EU countries in 2015, Poland with the share of energy from renewable sources in gross final consumption on the level of 11,8% took a position far behind Sweden (53,9%), Finland (39,2%), Austria (33,0%) and Denmark (30,8%) where the values of the indicator were highest. The lowest share of energy from renewable sources was recorded in the Netherlands (5,8%) and United Kingdom (8,2%). Since 2008 in Poland the share of renewable energy in gross final consumption has been on a constant but slight increase. It went from 6,9% to 11,3% in the years 2004-2007, and up to 11,8% in 2015. The observed increase of energy from renewable sources is also reflected in the growing diversification of these sources. The share of RES in gross final consumption often differs from the share in primary production.

## 5. The Analysis of the Similarity of the Primary Energy Production Structure in Poland to the Ones in the Selected EU-28 Countries

The analysis of the changes in the structure of primary energy production in Poland and selected EU-28 countries is based on data from the Eurostat energy balance 2010 and 2015 on a yearly basis. The structure of the production of primary energy in Poland and EU-28 is presented in table 1.

**Table 1: The Frequency Coefficient of the Structure of Primary Energy Production in Poland in the Years 2010 and 2015**

	Solid fuels	Oil (total)	Natural gas	Nuclear energy	Renewable energy	Wastes (non ren.)
<b>2010</b>	0.823617	0.010463	0.053811659	0	0.103139	0.008969
<b>2015</b>	0.802395	0.013473	0.055389222	0	0.121257	0.007485

Source: own elaboration based on Eurostat (2018)

A comparison of the primary energy production structure in Poland shows that the share of energy from renewable sources in 2015 was bigger than in 2010. In 2015 it was 2,1%, gas 5,5 %, and petroleum products 1,3%. In Poland there are no nuclear power plants. The basis of production in the discussed period were fossil fuels. In 2015 they accounted for 80,2% of total production. In order to analyze the intensity of changes in the sector structure of energy production, we use a measure determining structural changes proposed by Rutkowski (Rutkowski, 1981). It is a variability coefficient of the indexes of the analyzed aggregation's growth, which at the same time measures the irregularity of the increase of the aggregate's components (Skrodzka, 2016, p.867-874).

$$V_{t,t+\tau}^i = \left[ \sum_{j=1}^k f_{j,t+\tau}^i \left( \frac{f_{j,t+\tau}^i}{f_{j,t}^i} - 1 \right)^2 \right]^{\frac{1}{2}} \quad (1)$$

where:

$f_{j,t+\tau}^i, f_{j,t}^i$  - the structure index in moments  $t$  and  $t+\tau$ ;  $j=1,2, \dots, k$  - components of the structure aggregate;  $i$  - object number.

$V_{t,t+\tau}^i = 0$  indicates the lack of change in the structure between periods. The higher the value of the measure, the more significant the structural changes.

In the next stage of the analysis we will compare the sector structure of the primary energy production in Poland with the sector structure in the whole European Union. Object similarity measure are used in analysis of this type (Malina, 2004). The measure is based on the value of the cosine of the  $\alpha$  angle measured between the  $U_{t1}$  i  $U_{t2}$  vectors characterizing the state of the structure in respective periods  $t1$  and  $t2$ .

$$\cos \alpha = \frac{\sum_{j=1}^k f_{j,t}^1 \cdot f_{j,t}^2}{\sqrt{\sum_{j=1}^k (f_{j,t}^1)^2 \cdot \sum_{j=1}^k (f_{j,t}^2)^2}} \quad (2)$$

where:  $f_{j,t}^1, f_{j,t}^2$  - components of the structure indexes vector respectively for Poland and the European Union.

The values of the measure are normalized, but to interpret the structures similarity assessment level, we consider the angle represented by the calculated cosine. A big  $\alpha$  spread between the  $U_{t1}$  and  $U_{t2}$  vectors means significant structure changes in period  $t2$  in comparison to the structure in period  $t1$ . A small spread of the angle indicates slight structure changes in the discussed periods. In an exceptional case, when the compared structures are identical, the angle between the structure vectors is 0. When the cosine value tends toward 0, which means the angle tends toward  $90^\circ$ , the vectors represent increasingly different structures. Arbitrary ranges determining small, medium or high structure similarity were set. The values of the cosine function for the division of a  $90^\circ$  angle into 3 equal parts were assumed as the ends of the ranges:  $[0, \frac{1}{2}]$ - big difference in structures;  $[1/2, \sqrt{3}/2]$ - moderate diversification of the

structures;  $[\sqrt{3}/2, 1]$ - high similarity. The function is not linear with respect to the angle, so we need to take caution expressing the size of structure changes in percentage. An analysis of the structure similarities in the selected EU countries and in Poland in the years 2010 and 2015 (Skrodzka, 2016, p. 263-273). The results of the calculations are shown in table 2.

**Table 2: The Similarity Values of the Primary Energy Production Structure of Selected EU-28 Countries in Relation to Poland in 2010 and 2015, and the Dynamics of Structural Change Intensity  $V_{2010/2015}$  in 2015 Compared to 2010**

Country	Poland		$V_{2010/2015}$
	2010	2015	
Bulgaria	0.777495	0.781997	0.167987
Poland	1	1	0.075112
Czech Republic	0.943404	0.908233	0.182427
Denmark	0.069608	0.092786	0.255603
Germany	0.751891	0.786667	0.239704
Estonia	0.990401	0.991679	0.022821
Ireland	0.898334	0.830205	1.044046
Spain	0.232128	0.182847	0.241812
France	0.023319	0.027585	0.015421
Croatia	0.115653	0.162508	0.648089
Italy	0.140252	0.162845	0.208962
Netherlands	0.070819	0.081989	0.250643
Austria	0.133936	0.157032	0.096197
Romania	0.547643	0.466436	0.126107
Finland	0.262761	0.259576	0.070476
Sweden	0.103897	0.110886	0.074527
United Kingdom	0.17907	0.196366	0.513112

Source: own elaboration based on Eurostat (2018)

The analysis revealed a close similarity of the Polish structure of primary energy production in 2010 to: the Czech Republic, Ireland, Estonia, and in 2015 only to the Czech Republic and Estonia. A moderate similarity in 2010 was observed in: Bulgaria, Germany, Romania, and Finland, and in 2015: Bulgaria, Germany, Ireland. The other discussed countries show bigger structural difference in comparison to Poland. The next step in the analysis was to determine the intensity of structural change in the examined period according to the formula (1). The values of the used measure of the intensity of structural changes in 2015 in comparison to 2010 for the selected EU-28 countries are presented in table 2. Disregarding the change route and focusing on the two points in time it is possible to state that compared to 2010 in 2015 the majority of measure results have similar and quite low values which means a low intensity of change in the analyzed structures. The dynamics of change were more intense in: Ireland, Croatia and United Kingdom.

## 6. Conclusion

The paper presents the concept of sustainable development of energy industry as a process of sustainable, secure and effective supply of energy which is a significant element of sustainable development. It offers a comparison of leading indicators of the development of sustainable

energy in the area of sustainable consumption and production, climate and energy change and sustainable transport. One of the principal indicators for monitoring sustainable consumption and production of electric energy is the consumption of energy in households per capita. The lowest values of the indicator in 2015 was observed for Romania 2,2 GJ and Poland 2,7 GJ, the highest for Sweden 15,8 GJ, Finland 13,7 GJ and France 8,2 GJ. In the area of monitoring climate and energy change in 2015 the majority of countries saw a decrease in the total emission of greenhouse gases compared to the emission in the base year which means they realized their obligations to reduce greenhouse gases to support sustainable development. In the group of the analyzed countries, the lowest emission in 2015 compared to the base year was observed in: Romania 41,85%, Estonia 42,33%, Bulgaria 46,33%. The highest occurred in: Spain 115,84% and Ireland 107,68%. In the analyzed group of countries the share of energy from renewable sources in gross final energy consumption is constantly growing. The lowest share of renewable energy was observed in Spain (5,8%) and United Kingdom (8,2%), the highest in Sweden (53,9%), Finland (39,3%), Austria (33,0%) and Denmark (30,8%). The share of RES in gross final consumption often differs from the share in primary production. The study also analyzes the structure of primary energy production in sectors and its dynamics in Poland, and compares it to the structure in selected European Union countries in the years 2020 and 2015. It was discovered that the examined structures differ considerably and realize the set climate goals to a different extent. The Polish individual goal on the share of RES is 15% in 2020, and in 2015 it reached 11,8%. The most significant changes in the structure in the analyzed period took place in Ireland, Croatia and United Kingdom. Environment is the foundation for the functioning of the economy and society, and society is fundamental to the development of economy. The indicators of the sustainable development of energy are the background and a basis of information on a country's energy situation. They show socio-economic context which determines the progress in pursuing and reaching the sustainable development of energy industry which is an integral part of the European Union Strategy for Sustainable Development.

### **Abstract**

*Until the 23 June 2016 referendum, the European integration was characterized by continuous development, progress, and deepening. The possibility of a disintegration had, however, been opened up by the Treaty of Lisbon in 2007. As the latter having been drafted with the idea that Article 50 would never be used, there is a lack of in-depth schemes to allow the Brexit process to be smoothly managed. In such a situation, much depends on whether the negotiating parties have the necessary trust in each other and intent to optimize their future relationship. Today, it is quite unpredictable where negotiations will end up. But wherever they'll end up, lessons could already be drawn from why they had started and how they are being conducted. Concerning the future, as a 'cliff-edge' scenario would cause enormous harm to both the UK and the EU, the only reasonable guiding principle for them should be to act in accordance with the economic and social well-beings of the people they represent: i.e. to put aside perceived political interests, and focus on protecting jobs and businesses.*

**Keywords:** *Brexit, car industry, financial services, value chains, withdrawal negotiations*

**JEL Classification:** *F02, F13, F15*

### **1. Introduction**

The day of the Brexit referendum (23 June, 2016) undoubtedly represents a milestone in the history of the European Union: after decades of deepening and enlarging, this was the first time people of a sovereign member state decided to leave the integration. It is not yet clear whether Brexit means a turning point – in that it will trigger a process of disintegration – or provide an opportunity for the remaining EU27 to engage in a stocktaking exercise and consider alternatives for Europe's future.

Our aim with this paper – after giving a short literature review – is to highlight the main risks associated with the significant differences in the UK's and the EU' approach to the withdrawal negotiations on one side, and what such differences could lead to, i.e. a no-deal scenario, on the other. By using the critical analysis method and drawing from across the spectrum of economic activities the examples of car industry and financial services, identified as two of the sectors being among the most sensitive to changes in UK-EU trade relations, we demonstrate that a no-deal scenario would be a disaster, and a hard-Brexit would result in a lose-lose situation for both sides. To avoid this, we suggest to take the most sensitive sectors away from the general scope of the future agreement and negotiate a special deal for them.

## 1.1 Literature

Literature on the consequences of Brexit started to surge well before the referendum, and the momentum continues to this day. A common feature of all these contributions is that they have been producing estimates without knowing anything about how the future relationship between the EU and the UK will look like. Hence their tendency to focus on some headline outcomes like an X or Y percentage fall in economic growth, household income, foreign trade or business investment by a given year (typically by 2030). These papers depart from the assumption that the UK will, under any scenarios, inevitably suffer from Brexit. They usually consider three different scenarios: a 'soft' or optimistic one, under which the UK would maintain substantial access to the single market (Norway or Swiss model); a 'hard' or pessimistic one, with no deal at all at the end of the Article 50 negotiations whereby trade between the UK and the EU would fall back to WTO terms; and a 'semi-hard' one, lying somewhere in between the two extremes (Dhingra et al. 2016; Schoof et al. 2015).

Some early analyses on Brexit even contained guesses on both short and longer term, the latter being devoted to the three above scenarios, the former predicting uncertainties, holding back spending decisions and deterring FDI (Kierzenkowski et al. 2016). The short run guesses did not really come true. An illustrative example of the relationship between econometric models and reality was when the Bank of England had to upgrade its forecasts for UK GDP growth for 2017 significantly for the second time in just six months, due especially to the resilience of consumer spending following the vote for Brexit: shortly after the referendum, in August 2016, it predicted the economy would expand just 0.8 per cent in 2017, while in its revised forecast, in February 2017, it said GDP would grow 2 per cent (Bank of England, 2017).

Another type of literature that developed since the Brexit vote consists of sectoral analyses which, like the general ones, know nothing about the nature of the future relationship between the EU and the UK. But since they are based on the worst case scenario, they have at least the advantage of giving serious warnings to decision-makers about the risks a no-deal scenario would entail. (For a more detailed account, see Chapter 3)

As for the literature dealing with disintegration, the paper of Vollaard (2008) concludes that the patterns of integration and disintegration being not evenly distributed across the region, it seems unlikely the EU would fall apart into Westphalian states. Auer (2010) argues that the attempt to move towards a more federalist Europe, as before, is no longer feasible, as populism and ethno-centric nationalism are emerging in Europe *not despite* but arguably *in response* to its elites' cosmopolitan agenda. Webber (2014) suggests that the future of the integration is highly contingent upon the rise of anti-EU movements and Germany's attitude. In this context, it is discouraging to see how much the economically resurgent Germany is clinging to that the Eurozone is managed according to its priorities. To the extent that Berlin tries to assert its influence over EU policies, resentments against Germany may increase in other members.

As for the author's publications on Brexit, following the referendum in June 2016, he and her colleague were amongst the first to provide a detailed analysis of the background to and the context of the Leave vote (Somai & Biedermann 2016). Their paper reviews the deeper societal and economic reasons behind the British choice to quit the EU. They conclude that increasing income and wealth inequalities, growing anti-elite sentiment in British society, and first of all a British approach to the rule of law that is fundamentally different from the continental one have contributed to the final result of the referendum, rather than immigration which, non the less, had a significant impact on employee's pay level in certain sectors and regions.

## 2. The Main Danger

Among the risks associated with Brexit the worst one is related to the difference in the parties' approach to the negotiations. As a matter of fact, it was clear from the outset that views of the British government and the Commission differ significantly as to what topics and in what order negotiations should be conducted on, and what could be considered to be a final output. In order to illustrate this danger of divergence between their approaches, it is worth recalling some of the parties' pre-negotiation statements.

From the guiding principles for Brexit talks, set out first in Prime Minister Theresa May's so-called Lancaster House speech (in January 2017) and confirmed in the British Government's White Paper (a month later), it was clear that Westminster formulated their strategic goals with the intention of maintaining many fundamental elements of the status quo and the closest possible tariff-free economic and trading relationship between the UK and the EU in the future. It would involve providing certainty and clarity for businesses through ensuring free trade with European markets, protecting workers' rights, promoting the UK's excellence in science and innovation, maintaining the 'mini-Schengen' regime of the British Isles (UK, Ireland, Channel Islands and Isle of Man), etc. According to the White Paper, Westminster is being interested in delivering a smooth and orderly exit from the EU on the basis that, unlike most trade negotiations, the parties have initially got the exact same rules, regulations and standards. So, talks should not be about bringing together two totally divergent systems but about managing the continued cooperation between the UK and the EU (May 2017; UK Government 2017).

By contrast, documents reflecting the EU's approach to Brexit negotiations – European Council Guidelines (Consilium 2017a) and Directives (Consilium 2017b) – showed that the Commission was not focusing on how to ensure the closest possible relationship with the UK after Brexit, but was up to something else. As for illustration, here are two quotations:

- 'A non-member ... cannot have the same rights and enjoy the same benefits as a member'
- '... the four freedoms of the Single Market are indivisible and ... there can be no "cherry picking".' (Consilium 2017a, p. 3)

While the first statement is difficult to argue with – especially as a non-member can obviously not take part for example in decision-making about working out EU-regulations, developing EU-policies, and cannot participate in talks about the future of the EU with the same rights as a member – the second one seems to be much more problematic. The premise whereby the EU's single market – freedom of goods, capital, services, and labour – are indivisible, has no economic foundations. Theory even suggests that the four freedoms can be substitutes. This is particularly true for trade and migration, as the quantity of work embodied in a country's imports have much the same effect on local wages as if those products and services were being produced by immigrant workers. It is, however, correct to say that trade and migration may also happen to be each other's complements rather than substitutes. Just think of exports that are often accompanied by supporting services. So, by trying to restrict free movement, the UK also restrict trade. But this is hardly a reason for the EU to cause further damage on both sides by imposing trade barriers through a hard Brexit (Kohler-Müller, 2017).

One of the main differences that have emerged between the EU and the UK concerns the interpretation of Article 50 of the Lisbon Treaty. According to paragraph 2, '... the Union [the EU] shall negotiate and conclude an agreement with the State [the UK], setting out the arrangements for its withdrawal, *taking account* of the framework for its future relationship with the Union.' In the Commission's interpretation this means that first a withdrawal agreement is to be reached, and then it comes to discuss about future relationship (see '*phased approach*' in Consilium 2017a p. 1; and Consilium 2017b, p. 4). By this logic, it would first

be established the amount the British should have to pay as an exit bill – the amount that the EU claims the UK must pay in order to settle its outstanding financial obligations – and only then can talks start on the details of how UK businesses might have access to the European single market. In the meanwhile, the British are of the view that in case of no agreement, all EU law will cease to apply and they would be subject to no enforceable obligation to make any financial contribution at all (House of Lords 2017, p. 3). Similarly, it may seem pointless from the EU perspective to force an early agreement on the avoidance of a hard Irish border, including any physical infrastructure or related checks and control, as long as nothing can be known about the arrangements that will regulate bilateral trade.

Although the British government's interpretation of Article 50 has always been quite different from that of the Commission – considering that '*taking account*' means a simultaneous rather than sequential approach – it did not, however, refrain from discussing certain issues (notably citizens' rights, Irish border, financial settlement, relocation of EU agencies from Britain) earlier than other ones (mainly future relationship). The difference in the parties approach to the negotiations can best be shown by the fact, that according to EU Guidelines it was up to the European Council to determine whether sufficient progress has been achieved before allowing the negotiations to proceed to the second phase. But never and nowhere had been said about what should be considered *sufficient progress*.

In the light of the above, it was an almost unexpected event when, in early December 2017, negotiators adopted a joint report on the progress they had made in the first phase of the talks, even if, due to the European Council's own caveat that *nothing is agreed until everything is agreed* (Consilium 2017a, p. 3), commitments set out in the report are not at all binding. Everything depends on whether the parties can come to a compromise about their future trade relationship during the second phase of the negotiations. Nevertheless, it is a bad omen for the future that on the very day (15 December 2017) when the European Council decided to move to the second phase of the negotiations, it also supplemented its negotiating directives in a way which has been highly debatable from a British viewpoint. Concerning the so-called transition period – aiming at facilitating for both citizens and businesses to adapt to the changes entailed by Brexit – it puts the UK on unequal footing:

- as for the obligations, the UK should be regarded as if it were still a member state ('*the acquis*' ... as well as '*any changes*' ... to it having '*automatically apply to and in the UK*');
- but as for the rights, the UK would '*no longer participate in or nominate or elect members of the*' ... EU '*institutions, nor participate in the decision-making or the governance of the*' ... EU '*bodies, offices and agencies*'. (Consilium 2018, pp. 6-7)

This would oblige the British government to accept that free movement from the EU27, as well as the supremacy of EU law and the competence of the Court of Justice of the EU would continue during the whole transition period. The UK would even be prevented to become bound by any international agreements, unless authorized to do so by the EU (Consilium 2018, p. 7). It is not only something which seems totally unacceptable for the British government, i.e. of changing from being an important rule-maker to being a simple rule-taker nation, but also something that literally contradicts paragraph 3 of Article 50 ('*The Treaties shall cease to apply to the State in question from the date of entry into force of the withdrawal agreement*').

Among the risks associated with Brexit, an overestimation – in theory by both sides, but in practice especially by the EU – of their perceived political interests, and putting these interests before the real social and economic interests of the peoples they represent, is probably the worst thing that could happen. If negotiators fail to recognize this danger, it is quite possible that parties may not reach an agreement by the 29 March 2019 deadline, or walk away from

the negotiating table earlier. Such a scenario would, however, cause enormous damage to the economies on both sides, particularly to internationally embedded sectors.

### **3. Sensitive Sectors**

The dismemberment of the value chain – i.e. the segmentation of the production of a product into different stages and the distribution of these segments among various countries in pursuit of greater efficiency and maximizing profit on the basis of differences in factor endowments of the countries – does advance specialization, but also heightens the interdependence of different markets.

In this context, Brexit puts value chains in a particularly delicate position. What seems to be clear since UK's Prime's Lancaster House speech (May, 2017) is that the fundamental reasons behind Britain's desire to pull out from the European Union – e.g. gaining back control over laws (ending the jurisdiction of the European Court of Justice (ECJ)) and borders (ending free immigration of persons from the EU) – will prevent the UK from continuing to participate in either the Single Market or the Customs Union. Since none of the EU's existing trade agreements with third countries can, without endangering Britain's interests, be applied to Brexit – for there is no way to run an autonomous trade policy; or borders cannot be easily crossed; or the agreement does not apply to agricultural and food products and/or services; or access to the EU markets is conditioned on a large amount of money to be paid into the common budget; or the jurisdiction of the ECJ is not ended; or a combination of all the above (Stojanovic & Rutter, 2017, p. 25) – it is no wonder the UK Government is seeking a bespoke arrangement with the EU, which would include both an 'ambitious and comprehensive Free Trade Agreement (FTA) and a new customs agreement' (UK Government, 2017, p. 35).

The probability of obtaining such a bespoke arrangement is, however, compromised by two problems. The first one derives from the fact that the more comprehensive and deeper the agreement, the greater the chances for the UK side to lose control over laws and regulations – while the British are just at pains to get it back again. The second one has already been mentioned: it comes from the EU negotiating guidelines whereby a non-member – who is not even willing to accept the bloc's four freedoms (notably the free movement of persons) – cannot expect to "cherry pick" what it likes and wants from the European integration.

The only way out of this situation lies – at least for sectors where a sudden change in the status quo would involve the greatest financial and social damage – in trying to take them away from the main body (the general scope) of the future agreement and negotiate a special deal for them. Naturally, this method only works if both parties get something out of it. Now, let us present here two such sectors: the automotive industry, a special treatment of which would be in the interests of both the UK and the EU 27, but with more damage prevented for the latter; and the financial services sector, for which the opposite is true.

#### **3.1 Car Industry**

Car manufacturing is one of the most globally integrated industries in the world. As for its weight in the UK, it employs directly 0.5 percent of the national workforce, contributes approximately 1 per cent of the GDP, accounts for 12 percent of total exports of goods, and invests a yearly amount of 2.5 billion pounds into R&D expenditure (all data are for 2015). If, however, the UK withdrawal were being done under a cliff-edge scenario, EU's WTO-tariffs on vehicles (10% for cars and 2.5-4.5% for parts) would put British exports at an immediate competitive disadvantage. Add to this the cost of customs checks at the border (€100-150 per

car) and a further 6 percent for the administrative and compliance costs of trade with the Union, to imagine delays and other damages such change would involve to the both *lean* and *just-in-time* production system of the automotive industry (SMMT 2016).

It's, however, not only the British car industry that would be seriously damaged. According to a recent study (Deloitte, 2017), if constructors passed all costs incurred by Brexit on to consumers, price for a car in the UK would increase by €3,700, and by as much as €5,600 for the ones manufactured in Germany (45% of German exports being premium models). As a result, the British market would shrink by 550,000 vehicles (-19%), of which 255,000 units (>46% of the decline) would have to be suffered by German constructors alone. In short, a cliff-edge scenario for Brexit would, by putting 18,000 jobs at risk, have a similar negative effect on German automotive industry as did the financial crisis in 2009.

All the above can, of course, be avoided if Brexit talks were conducted in the spirit of mutual goodwill. This should surely be a precondition not the least because the automotive industry – due to costs related to the technological constraints inherent in it – can *'only take (re-)location decisions once in the 7-year lifecycle of a new product'* (PwC, 2016). If there is no chance for a comprehensive free trade agreement being concluded by the leave date, one should perhaps look for a temporary sector-specific solution – e.g. by transforming UK production sites into special economic (i.e. duty-free) zones – in order to remove uncertainty for the industry and make sure that the investment cycle remains unbroken until a lasting solution can be found.

### **3.2 Financial Services**

The financial services industry directly provides 7 percent of the British GDP, and employs 1.1 million people. When related professional services (i.e. management consultancy, legal services and account services) are added, these data reach 11.8 percent of GDP and 2.18 million people or 7.4 percent of UK labour force. The larger 'industry' contributes £67 billion in taxes (or 11% of total UK tax receipts) and generates a trade surplus of £72 billion per year (all data are for 2014). Annual revenue from financial services are about £200 billion, of which 46-49 percent comes from domestic market, 21-23 percent relates to the EU, and the remaining 30-31 percent to the rest of the world (UK Parliament, 2016a, p.12).

The single biggest risk to the UK's financial services sector posed by Brexit comes from the uncertainty about whether and to what extent British businesses could retain access to the European single market. Ideally, they need two pieces of information: what the UK's future relationship with the EU will look like and what will be the bridge arrangement between leaving and getting to that relationship. In the absence of clarity, firms may preempt uncertainty by restructuring or relocating on the basis of a worst-case scenario. But not only the City would suffer, as one cannot with impunity (i.e. without the risk of increasing costs and complexities) unpick a highly developed ecosystem such as exists in London. The City has evolved over decades into what the profession recognizes as the world's leading financial center where hundreds of banks and thousands of different financial services companies are available to consumers, investors and businesses, and the significant interconnectedness of the different service providers enables the business sector to enjoy the efficiencies of scale stemming from the effect of compression, i.e. having all their transactions be packaged together, and having it all sitting on a single trading venue. In this environment, the concentration of capital, infrastructure and knowledge permits the companies to profit from the advantages of cost efficiency under unique conditions (UK Parliament, 2016b, pp. 5-11).

So, should the Commission attempts for example to repatriate the clearing of euro-denominated derivatives to the Eurozone, it will not only put at risk thousands of jobs in the

UK, but also increase the cost of trading for banks by several tens of billions of euro across a 5-year period following Brexit, i.e. a lose-lose situation for both the UK and the rest of the EU. The calculation is based on the assumption that fragmenting LCH's (London Clearing House, the world's largest clearing house) pool of interest-rate derivatives would change the price of every swap – the most commonly used type of contract – by one basis point (Hadfield, 2017).

As the financial services sector is becoming more and more globally organized – major players already responding to the Financial Stability Board, Basel, IOSCO and Dodd-Frank, etc. – and passporting rights might, in the foreseeable future, be replaced with globally regulated equivalence systems, it would be a workable way out of the Brexit dilemma, if the negotiating parties were reconciled themselves to the trend of globalization. Here again a more flexible approach could lead to a mutual recognition of each other's regulatory regimes.

#### 4. Conclusion

The process of the Brexit negotiations so far (slow progress and provisional solutions to certain chapters) show that the parties formulate their positions on the basis of fundamentally differing interests. The British want to change the EU-UK relationship only as much as they think to be necessary considering the results of the exit referendum and the essential points of the exit campaign, i.e. taking back control over laws and borders, and restricting contribution to the common European budget. However, the Commission, enjoying the confidence of the French-German tandem, and insisting on the dogma of the inseparability of the four freedoms, wants a significantly more distant relationship with the UK. It fears that if the British could arrange their withdrawal from the EU with no or minimal harm caused to their economy, i.e. an exit not deterrent enough to stop other member states from reconsidering their own situation within the club, this could lead to the total decomposition of the European integration.

Today, it is quite unpredictable where Brexit negotiations will end up. At any rate, it is scary to see how big the gap between the positions of the negotiating parties (presented in Chapter 2) still remains. Arising from the loss of a military and nuclear power, and the biggest advocate of liberal thoughts, damages to the EU, at least in the long run, could certainly appear at ideological, political and geopolitical level (Ševčíková, 2016). As for the economic level, the examples of car industry and financial services were chosen in this paper to demonstrate how a cliff-edge withdrawal of the UK from the EU would on either or both sides cause serious damage. Naturally, the list of the economic activities is much longer. One can for example mention the meat industry which would face the highest (on average close to 50%) tariffs of all sectors under WTO rules, consequently, leading to a greater disruption to trade flows than that caused by the Russian import ban in 2014, and a loss of at least 32,000 in the EU27 (UECBV 2017). Or, the fishing sector, one of the more contentious and complex question of which being the access to fisheries resources and repatriation of responsibility for regulation within the UK's 200 mile Exclusive Economic Zone (EEZ), having in mind that, yearly, EU27 boats catch seven times more fish by weigh (and five times by value) from the UK EZZ than UK boats do from the EU27 EZZ (Phillipson & Symes, 2018).

On the basis of the above, as neither party would benefit from an economic downturn in the other, negotiations should, in theory, focus on protecting jobs and businesses in the whole region, and thus head towards the best possible future relationship between the United Kingdom and the European Union. Unfortunately, as there is no guarantee such an optimistic scenario will happen, further research should be conducted in a wider range of sectors.

### **Abstract**

*The paper deals with analysis of consumer behaviour on the digital music market. The development of music industry over the last two decades is one of transformation: from physical to digital; downloads to streaming; ownership to access. The main goal is to investigate how such technological transformation has affected consumer behaviour of listeners across distinct age groups (Generation X and Generation Y) and across two EU markets (Czech, British). The study is based on on-line survey conducted in both countries. The findings indicate the substantial effect of age categories and country of residence on discussed attributes of consumer behaviour (intensity of listening to digital music, platform of listening to digital music, willingness of monthly payment for digital music). This article also discusses the tendency to pirate download.*

**Keywords:** digital music market, EU markets, Generation Y, Generation X, listeners

**JEL Classification:** M31, C83, C40

## **1. Introduction**

The development of the recorded music industry over the last two decades is one of transformation: from physical to digital; downloads to streaming; ownership to access. The industry is now working with its partners on another, ongoing transformation: from years of decline to sustainable growth.

### **1.1 The Characteristics of Digital Music Market**

In 2016, the global recorded music market grew by 5.9%, the fastest rate of growth since IFPI began tracking the market in 1997 (IFPI, 2017). This was a second consecutive year of global growth for the industry with revenue increasing in the vast majority of markets, including nine of the top ten. This growth, however, should be viewed in the context of the industry losing nearly 40% of its revenues in the preceding 15 years (IFPI, 2017).

In the last decade, digitization has dramatically affected most of the media industries. The traditional music storage style of the phonograph disk has been changed by digital storage, due to the new e-era digital technology and the micro - miniaturizing of music storage and playing devices. Consequently, the dissemination of music does not rely on the phonograph any longer. Instead, people can download music from websites or listen to music online (Lin, Shih, Tzeng, Yu, 2916). Digital technologies have allowed drastically reduce the costs of copying and disseminating information. In the case of the music industry, these costs reductions have led

to major gains for consumers who can now easily enjoy and benefit from a wider range of products at a minimal cost (Aguiar, Martens, 2016).

Elberse (2010) differentiates between three categories of product-service offered by the music industry: the physical album, the digital album and the digital single (or track). The first one is related to product and its sales are clearly decreasing (with some exceptions during Christmas periods). The second (also called bundled digital music) does not seem to have an important presence in the market. Finally, the evolution of the sale of digital music as a single song or track (unbundled music) is clearly dominant.

Streaming (unbundled music) has been the clear driver of growth on the digital music market with revenues surging by 60.4% (IFPI, 2017). With more than 100 million users of paid subscriptions globally, streaming has passed a crucial milestone. It makes up the majority of digital revenue, which, in turn, now accounts for 50% of total recorded music revenues (IPFI, 2017).

Music streaming services can be classified into different types according to their revenue model and streaming mode (Kim, Nam, Ryu, 2017). First, streaming services can be split by revenue source as an advertisement-based free model or a subscription-based streaming model. Streaming service providers can generate revenue by selling advertising while offering services free of charge or by charging a monthly subscription fee to users while providing streaming without advertisements (Wlomert & Papies, 2016).

Second, streaming services can be categorized as either streaming radio or on-demand streaming based on the kind of services they provide. Streaming radio allows users to choose among predetermined playlists, but they cannot listen to individual songs of their choice. On-demand streaming allows users to search and listen to individual songs of their choice in addition to choosing from predetermined playlists. Streaming radio services often employ the ad-based free model, for instance Pandora, while on-demand streaming services usually choose the subscription model, as in the case of Apple Music and Spotify (Kim, Nam, Ryu, 2017).

Parry, Bustinza, Vendrell-Herrero (2012) hold that subscription model in the music industry could take two forms, similar to mobile phone service contracts. First, "pay as you go" describes customers who are under no obligation or incentive to use the service and are free to choose when, where and how. They are paying only per downloaded track. The attractiveness of this business model is that in transactional terms it replicates the retail outlet experience and so can potentially remove some of the barriers to entry such as commitment to purchase or organizational membership. Second, "pay monthly" represents a model where the consumer commits to paying a monthly fee, potentially over a fixed period, and in return gains access to an allotted music service. In this business model, with increased usage unit price reduces to a point that should be lower than that of the pay as you go model, with a maximum limit to the monthly consumption. This business model supports increased consumption and relies on customers overestimating how much use they will make of the service.

Digital music industry faces big threat represented by illegal downloading of digital files. No longer limited to sharing physical copies, millions of virtual strangers can share music files via the Internet (Borja, Dieringer, Daw, 2015). This digital piracy decreases profits and earnings both record companies and artists, but most importantly, it distorts the dynamic market of digital music.

Digital music industry is protected in EU by some legal instruments, such as the Directive on the enforcement of intellectual property rights ('IPRED') which was adopted in April 2004 (European Commission, 2018). The Directive requires all EU countries to apply effective,

dissuasive, and proportionate remedies and penalties against those engaged in counterfeiting and piracy. Following the evaluation of IPRED, in November 2017 the Commission adopted the Guidance Communication clarifying the provisions of IPRED where there have been differing interpretations in EU countries. The guidance is based on ruling by the EU Court of Justice and best practice developed in EU countries (European Commission, 2018).

In April 2016, a joint study by the OECD and EUIPO (the EU Intellectual Property Office) was undertaken that illustrated an exponential growth of counterfeits and pirated goods worldwide. In particular, the OECD's estimates of counterfeit and pirated products have increased from \$250 billion in 2007, to up to \$441 billion in 2013, which represents approximately 2.5% of world imports (OECD/EUIPO, 2016). In the same year, imports of counterfeit and pirated products into the EU amounted to nearly \$116 billion, which represents up to 5% of EU imports (OECD/EUIPO, 2016).

### ***1.2 The Behaviour of Age Generations on Digital Music Market***

There has been a dramatic music retailing shift within the last decade. The post-war Baby Boomer generation born between 1945 and the early 1960s has preferred interpersonal, in-store purchase of records (or discs), while Generation Y (Gen Y) consumers, born from the 1980s onwards, sticks on digital file downloading of music files or tracks (Fjelstul et al., 2009; Roberts and Manolis, 2000, McIntyre, 2011). Generation is a key segmentation driver affecting behaviour on digital music market.

Generation is described as a group of individuals who are born in the same time period (Palese et al., 2006), have common geographical area and significant events (Kupperschmidt, 2000) and similar culture (Palese et al., 2006; Jain, Pant, 2012). Due to the same life span, each generation has gone through the same social events and external influences in their formative years, thus creating similar life experiences (Kupperschmidt, 2000; Jain, Pant, 2012). Crispell (1993) has classified six generations, but this contribution displays a shift in the digital music market between Generation X and Generation Y.

Squeezed between the Boomers and Millennials, Generation X is also known as Xers, Baby Busters (Kardes, Cronley, Cline, 2015). Members of this generation were born between 1965 and 1976. This generation is described as socially insecure and lacking in solid traditions (Jain, Pant, 2012). Generation X spends more time watching television and sharing their experience with their social group via media. Generation X uses email rather than social media such as Facebook (Strutton et al., 2011, Jain, Pant, 2012).

Generation Y are also known as Millennials (Klapilová Krbová, Velčovská, 2016). Generation Y consists of individuals born between 1976 and 1995. Members of Generation Y were influenced by these technologies during their adolescence and later, but using these technologies during their childhood was not usual (Pawlasová, Spáčil, Valečková, 2014). They are the most tech savvy generation and are online simply 24/7 (Pawlasová, Klézl, 2017). They focus on brands, friends and digital culture (Muskat, M., Muskat, B., Zehrer, Johns, 2013).

## **2. Problem Formulation and Methodology**

This paper explores the difference this move from product based to digital platforms has made for consumer groups. Since the rise of music on the internet the record industry has reported falling total sales revenues. This has occurred at a time when technology has radically

increased choice, availability and the opportunity for the consumer to purchase music (Parry, Bustinza, Vendrell-Herrero, 2012).

### **2.1 Problem Definition**

McIntyre (2011) has demonstrated the impact of age cohorts on the acceptance and perception of digital music. So, first goal is to investigate how such technological transformation has affected consumer behaviour of listeners across distinct age groups (Generation X and Generation Y). The second goal is to explore the behaviour of digital music listeners on two EU markets (Czech, British). UK market was chosen for survey because it belongs among the three largest performance rights markets (the revenue generated by the use of recorded music by broadcasters and public venues) (IFPI, 2017). Czech market is smaller market of post-communist country with some tendency to piracy of digital music streaming.

### **2.2 Research Methodology**

For this research on-line questionnaire has been applied. Forms by Google (for the British side) and website of VypInto.cz (for the Czech side) were used to collect all necessary data. The mix of convenience sampling and quota sampling has been selected as the most suitable type for this study. Quota was set for number of respondents from each country (100 respondents). Quota was kept on the British market, while number of respondents on the Czech market is slightly lower in comparison with plan (see Tab.1). The other segmentation criteria (gender and age) have not been under full control due to convenience sampling. But number of respondents in each subcategory is sufficient for cross tabulation. Sample size was 198 respondents.

**Table 1: Structure of Sample**

	<b>Male</b>	<b>Female</b>	<b>Gen Y</b>	<b>Gen X</b>	<b>CZE</b>	<b>UK</b>
<b>Absolute frequency</b>	74	124	137	61	93	105
<b>Relative frequency</b>	37%	63%	69%	31%	47%	53%

Source: own elaboration

Data collected from both countries were firstly edited and coded. Then data were analysed via statistical package of IBM SPSS Statistics version 25. All variables obtained from questions (preferred devices for listening to the music, downloading the digital music, preference of digital platform for listening to the music) were nominal (non-metric) so non-parametric tests were used for testing. Chi-square statistics was applied to test statistical significance (see Tables 3, 5 and 7) of the observed association in cross tabulations (see Tables 2, 4 and 6). It assisted us in determining whether a systematic association exists between two variables. First variable was always the attribute of consumer behaviour on digital music market, second one expressed gender, age cohort (generation) or country residence.

### **3. Problem Solution**

The results are structured into three sections: (1) preferred devices for listening to the music, (2) downloading the digital music and (3) preference of music digital platform.

### 3.1 Preferred Devices for Listening to the Music

Seven types of devices have been named as vehicles for listening to the music. Generally the respondents mostly prefer multifunctional devices (PC laptop, smartphone) (see Table 2). The importance of car stereo, radio and TV for listening is diminishing. The position of MP3 player is now marginal in comparison with the first decade of 21<sup>st</sup> century and practically has not been mentioned. There are two main reasons for sales decline. Firstly, if consumers don't listen to music that often, a smartphone will be more than good enough. Secondly, smartphones allow consumers listen to music from music subscription services like Spotify, Deezer, Tidal, Amazon Music or Apple Music (Hoffman, 2018).

**Tab 2: Preferred Devices for Listening to the Music Based on the Segmentation Criteria**

	Male	Female	Gen Y	Gen X	CZE	UK
<b>PC/laptop</b>	72%	77%	81%	56%	79%	70%
<b>Smartphone</b>	72%	74%	83%	42%	69%	77%
<b>Car stereo</b>	58%	44%	43%	67%	53%	45%
<b>Radio</b>	40%	44%	40%	51%	47%	39%
<b>TV</b>	24%	30%	24%	37%	32%	23%
<b>Tablet</b>	22%	15%	15%	29%	8%	28%

Source: own elaboration

There are not statistically significant gender differences concerning with preferred devices for listening at all (see Tab 3). The slight differences in preferences of devices between Czech and UK listeners have not been statistically proved just with the exception for tablet. The impact of generations on device preference is really strong and statistically justified (see Tab 3). Statistically significant differences are expressed by bold letters. For Generation Y smartphones and PC/laptops are decisive devices for listening to the music. Conversely, cars stereo is used as key device for generation X (see Tab 2). It should be also reasoned by higher level of car ownership among Gen X consumers.

**Tab 3: Significance Test for Differences in the Preference of Devices for Music**

	Gender differences	Age differences	Country differences
<b>PC/laptop</b>	0,463	<b>0,001</b>	0,196
<b>Smartphone</b>	0,745	<b>0,000</b>	0,208
<b>Car stereo</b>	0,084	<b>0,006</b>	0,258
<b>Radio</b>	0,615	0,197	0,279
<b>TV</b>	0,397	0,103	0,156
<b>Tablet</b>	0,245	<b>0,043</b>	<b>0,000</b>

Source: own elaboration

### 3.2 Downloading the Digital Music

Downloading digital music was measured on descriptive scale with for levels and was based on self-assessment of listeners. No matter the soft data has been used for finding the differences

in consumer behaviour the results display the substantial gap in the accepting digital music. Definitely, generation differences in preference of digital music are visible (see table 4) and also statistically proved (see Tab 5). 98% of respondents from Gen Y download digital music compared with of 71% of respondent from Gen X. Moreover, nearly quarter of consumers from Gen X do not plan to download digital music in the future.

**Tab 4: Downloading the Digital Music Based on the Segmentation Criteria**

	Male	Female	Gen Y	Gen X	CZE	UK
<b>Yes, I do it frequently</b>	72%	69%	88%	30%	69%	71%
<b>Yes, but not very often</b>	19%	20%	10%	41%	26%	14%
<b>No, but I will possibly do so in the future</b>	1%	2%	0%	7%	0%	4%
<b>No, and I have no plan to do so</b>	8%	8%	1%	23%	5%	10%

Source: own elaboration

Findings also show statistically confirmed country differences (see Tab 5). Although the share of frequent listeners of digital music is nearly the same in both countries (see tab 4), there are twice more moderate listeners in the Czech Republic. The share of listeners who refuse downloading digital music in future is slightly higher in UK than in Czech Republic (see Table 4).

**Tab 5: Significance Test for Differences in the Downloading the Digital Music**

	Gender differences	Age differences	Country differences
$\chi^2$ test	0,954	<b>0,000</b>	<b>0,037</b>

Source: own elaboration

### ***3.3 Preference of Digital Platform for Listening to the Music***

There are many digital platforms that constitute different categories of music consumption: music downloading (digital stores), music streaming (subscription services, social sound platform), music video streaming, and online radio. The downloading and streaming categories could be further divided into licensed and unlicensed websites (piracy download/copy).

Music videos generate definitely the decisive platform for each segment no matter of gender, age and country residence (see Tab 6). You Tube is a key brand of music videos channel. Tendency to pirate download is viewed namely among members of Gen Y and Czech listeners (see Tab 6) and is statistically confirmed (see Tab 7). From country point of view the more listeners use subscription services and digital stores the less they look for pirate downloading. Gen X was ready to buy vinyls and compact discs in past so they almost do not need download music in pirate way. Also members of Gen X prefer digital stores to subscribe services because they got to use to have the complete album of their favourite band or interpreter.

**Tab 6: Preference of Digital Music Platform Based on the Segmentation Criteria**

	<b>Male</b>	<b>Female</b>	<b>Gen Y</b>	<b>Gen X</b>	<b>CZE</b>	<b>UK</b>
<b>Music videos</b>	80%	85%	85%	77%	91%	75%
<b>Pirate download/copy</b>	53%	54%	62%	28%	62%	45%
<b>Subscription services</b>	33%	29%	37%	12%	19%	43%
<b>Online radios</b>	26%	27%	25%	33%	29%	24%
<b>Digital stores</b>	32%	16%	22%	23%	15%	30%
<b>Social sound platform</b>	23%	15%	20%	12%	13%	23%
<b>Other</b>	3%	2%	2%	5%	2%	2%

Source: own elaboration

**Tab 7: Significance Test for Differences in the Preference of Digital Music Platform**

	<b>Gender differences</b>	<b>Age differences</b>	<b>Country differences</b>
<b>Music videos</b>	0,469	0,213	<b>0,004</b>
<b>Pirate download/copy</b>	0,938	<b>0,000</b>	<b>0,024</b>
<b>Subscription services</b>	0,555	<b>0,002</b>	<b>0,001</b>
<b>Online radios</b>	0,826	0,318	0,447
<b>Digital stores</b>	0,017	0,842	<b>0,015</b>
<b>Social sound platform</b>	0,226	0,200	0,102
<b>Other</b>	0,601	0,229	0,982

Source: own elaboration

#### 4. Conclusion

The growing importance of digital music consumption calls for a better understanding of the relationship between the different consumption channels available to consumers. Nonetheless, it is ultimately consumer preferences that determine which business model will be successful and, consequently, in which direction the streaming industry will progress.

Findings have shown that age is a key indicator for display of listener behaviour. 98% of respondents from Gen Y download digital music in comparison with listeners from Gen X (71%). Both generations prefer almost different devices for listening and different digital music platforms. Country differences concern just with digital music platforms (see Tab 6). Gender differences practically do not exist only with exception of digital store preference.

Understanding the product attributes valued the most by consumers and segmentation profile will provide important insights into formulating an optimal business model and predicting the development of the digital music industry. The future of digital music industry strongly depends on level of music piracy (copying and downloading of music illegally) which is considered a serious problem. This is extremely concerning with Gen Y listeners and Czech listeners who admit higher level of illegal downloading. The problem of music piracy goes beyond the current dollar losses. It is also about the economic, legal, and social distortions, and the market inefficiencies anchored in the act of stealing copyrighted songs.

In order to combat music piracy, governments and the music industry should target young consumers regarding law and risk awareness, recognition of artists' harms and losses, and strengthen law enforcement (Borja, Dieringer, Daw 2015).

### **Abstract**

*In spite of a recent slight recovery in the European Union, some issues such as very high public debt to GDP in some EU member countries remain also in post-crisis period. Public debt has become a highly debated economic issue in recent years due to the European debt crisis, which was especially strong in euro area countries. Reduction of the excessive public debt has moved to the forefront among the economic policy challenges facing many of European Union countries in recent years. An accumulation of high levels of public debt can have severe negative consequences. One of them is a negative correlation between debt and economic growth as most existing empirical literature on this object has found. Sustainability of the debt depends not only on its size, but also on its structure. The structure of public debt may become a channel or source of vulnerability to the real economy and the financial system. In this respect, this paper analyses debt decomposition – residency of creditors, currency which is used to issue debt and original maturity of debt instrument – on recent available data. According to our findings, the debt share held by non-residents was significant for most of the European Union countries; only two countries issued more than 50% of their debt in foreign currency and the long-term securities were the most used debt instrument.*

**Keywords:** *currency, economic growth, euro area, European Union, debt holders, debt-to-GDP ratio, maturity, public debt, sovereign debt crisis, structure of public debt*

**JEL Classification:** *E62, H63, O40*

### **1. Introduction**

In 2008, the world economy faced its most dangerous crisis since the Great Depression of the 1930s. The outbreak of the financial crisis very negatively afflicted economic agents in many countries. The crisis has been unusual in its global nature, affecting advanced countries and countries integrated, with the euro area most affected. Initially, this crisis hit the real economy, which suffered from the failure of large financial institutions, and later expanded its influence on state finances. In this regard, the financial crisis in Europe has transformed into a sovereign debt crisis, beginning in 2009, and has an effect on most EU Member States. The government debts in many European countries began to rise and peaked in 2014, when reached on average 91.8% of GDP in the euro area and 86.5% in European Union as a whole. Such debt levels can carry risks for economic growth prospects and financial stability. However, there are also additional potential risks arising from a structure of public debt. Therefore, the aim of this paper is to analyse debt decomposition – residency of creditors, currency, which is used to issue debt and original maturity of debt instrument – on recent available data for European Union countries. These are information useful in assessing debt sustainability.

The rest of the paper is organized as follows. Section 2 describes European sovereign debt crisis and evolution of public debt in European Union during 2002-2016. Section 3 presents the decomposition of public debt in European Union according to debt holders, currency denomination and financial instruments and their maturity on data from 2016. Section 4 concludes.

## **2. Development of Public Debt in European Union**

In 2007, EU economies, on the surface, seemed to be doing relatively well – with positive economic growth and low inflation. Public debt was often high, but (apart from Greece) it appeared to be manageable assuming a positive trend in economic growth. However, with a recession that hit European countries, state finance in some countries collapsed.

### **2.1 European Sovereign Debt Crisis**

The European debt crisis was a series of debt crises that began with the global financial crisis of 2008 and hit several Eurozone members. It started in 2009 when Greece announced its actual budget deficit was 12.9% of gross domestic product, more than quadruple the 3% limit mandated by the European Union. Credit rating agencies lowered Greece's credit ratings. Investors responded by demanding higher yields on Greece's bonds, which raised the cost of the country's debt burden and necessitated a series of bailouts by the European Union and European Central Bank. The markets also began driving up bond yields in the other heavily indebted countries in the region, anticipating problems similar to what occurred in Greece. The Greek debt crisis soon spread to the rest of the Eurozone, since many European banks had invested in Greek businesses and sovereign debt. In three years, debt crisis escalated into the potential for sovereign debt defaults from Portugal, Italy, Ireland and Spain.

In 2010 the European Union and International Monetary Fund disbursed 110 billion euros in loans over three years to Greece. In 2011, Greece's creditors agreed to take a large haircut on their debt of 53.5% of the face value to avoid a disorderly default by Greece on its debt. The first bailout was followed by two more, - in February 2012 (130 billion euros) and July 2015 (86 billion euros distributed through 2018). In 2017, tensions over Greece's third bailout grow as the IMF warns that the country's debt is unsustainable (Saini-Davies, 2017).

Other countries, like Ireland, Portugal, and Italy, had also overspent, taking advantage of low-interest rates as Eurozone members. As Lane (2012) points out, Spain was a little different. The government had been fiscally responsible, but the 2008 financial crisis severely impacted its banks. They had heavily invested in the country's real estate bubble. After Spain joined the euro, the country experienced a long boom, underpinned by a housing bubble, financed by cheap loans to builders and homebuyers. House prices rose 44% from 2004 to 2008, at the tail end of a housing boom. Since the bubble burst they have fallen by a third. The size of the banks' problems and a recession, that hit Spanish economy, meant the country had to turn to its fellow Eurozone members for help. By 2012, Spain was forced to request a bailout, and EU leaders agreed to use Eurozone funds (100 billion euros) to provide the Spanish government to recapitalize its struggling banks. The loans will come from Eurozone funds set up to help members in financial distress: the European Financial Stability Facility (EFSF) and the European Stability Mechanism (ESM).

According to Whelan (2015), a similar situation also occurred in Ireland. Ireland had combined a long period of high economic growth and low unemployment with budget surpluses. A population growing, incomes expanding rapidly and historically low interest rates, increased

demand for housing. The acceleration in housing activity after 2002 was largely financed by the Irish banks. As house prices fell in 2007, the collapse in housing construction occurred and unemployment jumped, resulting in a large loss in income tax revenues. The bursting of the bubble in the real estate market turned to a banking crisis in 2009. In 2010, economic growth was significantly negative, the budget deficit was out of control and the debt to GDP ratio had risen to over 100%. Therefore the European Union, International Monetary Fund and the Irish state agreed to a €85 billion rescue deal made up of €22.5 billion from the IMF, €22.5 billion from the European Financial Stability Facility, €17.5 billion from the Irish sovereign National Pension Reserve Fund (NPRF) and bilateral loans from the United Kingdom, Denmark and Sweden.

In the Portugal, financial crisis worsened the current crisis of Portuguese economy that has begun in 2002. With decreasing of interest rates, the degree of public and private indebtedness reached very high levels. Portuguese government bond yields raised to unsustainable levels as Fitch and Standard & Poor's cut their ratings of Portuguese sovereign debt in March 2011 (De Santis, 2012). In April 2011, Portugal became the third European Union country to apply for EU and IMF financial assistance worth 78 billion euro to help it cope with its budget deficit. In 2013, the Portuguese government approved more spending cuts, mainly affecting public-sector employees' wages, conditions and pensions, in order to avoid a second international bailout.

While the Eurozone debt crisis has been a factor, Italy's problems are more fundamental with the economy having grown little since the introduction of the Euro in 1999. Since joining the Euro, Italy has seen its relative competitiveness decline. However, in addition to these weaknesses, the rapid increase of the Italian state's indebtedness has rendered the country's fiscal position unsustainable. Italy crossed the 100 per cent debt-to-GDP-ratio threshold. This led investors to view Italian debt bonds as a risky asset. The austerity packages (spending cuts) followed, nevertheless, the Italian debt continued to rise and Italy recorded the government debt equivalent to 132 percent in 2016. (Engler and Klein, 2017)

As will be clear from the analysis above, the sovereign debt crisis is deeply connected with the banking crisis and macroeconomic imbalances that afflict the euro area. According to Lane (2012), there are three phases in the relationship between the euro and the European sovereign crisis. First, the initial institutional design of the euro plausibly increased fiscal risks during the pre-crisis period. Second, once the crisis occurred, these design flaws amplified the fiscal impact of the crisis dynamics through multiple channels. Third, there were also the restrictions imposed by monetary union. Crisis management institutions were also missing.

## ***2.2 Development of Public Debt in 2002 - 2016***

In the years before the outbreak of the crisis, average public debt-to-GDP ratio in EU reached values around the level of Maastricht criteria. The average level of public debt-to-GDP ratio in euro area was higher by approximately ten percent. Just before the outbreak of the crisis in 2005-2007, ratios of public debt was decreased. In 2007, public debt in the euro area reached on average 64.9% of GDP and in the whole European Union 57.5%. When the crisis started to impact the euro area, its Member States reacted with important stimulus packages and injections of public money into their banking systems (see part 2.1), which in many countries increased public debt and deficit well beyond the Maastricht reference values. Public debt continued to increase as a result of the measures taken during the crisis, in 2014, it peaked at 91.8% of GDP on average in the euro area and 86.5% in European Union as a whole (see Figure 1). Since then the public debt has declined slightly.

**Figure 1: Government Gross Debt-to-GDP Ratio in EU-28 and EA-19, 2002 - 2016**

Source: Eurostat (2018), author's elaboration

Public sector deficits and the burden of the public debt are once again at the centre of macroeconomic policy debate. However, the high public debts are not new phenomenon in some European countries, as we can see in Table 1.

**Table 1: Public Debt to GDP Ratio, 8 EU Member States, 1910 - 2015**

	1910	1930	1950	1970	1990	1995	2010	2015
<b>Austria</b>	67.1	19.3	22.1	10.6	46.0	67.9	82.4	84.3
<b>Belgium</b>	49.6	57.5	73.7	48.3	106.6	130.5	99.7	100.6
<b>France</b>	79.6	142.9	27.4	12.4	35.2	55.8	81.6	95.8
<b>Germany</b>	46.6	n.a.	17.5	17.4	41.0	54.8	80.9	70.9

<b>Average</b>	61.9	69.0	49.6	26.7	60.6	78.8	77.4	86.4

Source: 1910-1990: Salsman, R. M. (2017); thereafter, Eurostat (2018)

Table 1 provides more historical context on public debt, depicting trends in public debt/GDP ratios for eight EU Member States over the past century. These countries reached the lowest levels of debt in the 1970s, nearly 27 percent in average. We can see in Table 1 that some countries like France, Italy and Netherlands had public debts sometimes over a one hundred percent early 20<sup>th</sup> century. It is known that governments incur most of their debt during or immediately following major wars and use peacetime conditions to reduce the debt-output ratio. However, the public debts increased also in the peaceful period after World War II. In 1980s, it was due to recessions accompanied by government deficits. In 1990s, a debt growth was conditioned also by the political-budget cycles. According to Janků (2016), the existence of the political-budget cycles causes significant macroeconomic losses, e. g. an unnecessary increase in the government deficit and debt at the time of the elections. Author claims that some of the EU Member States with a lower credibility and transparency of fiscal policy - Czech Republic, Estonia, Hungary, Italy, Poland, Portugal, Slovakia and Slovenia - are particularly vulnerable to the political-budget cycle.

The situation worsened even further after the outbreak of the financial crisis. In recent years, the highest debt ratio from these eight European countries is that of Italy, nearly 132 percent

in 2015, increased more than four times from 1970. The second largest ratio in 2015 is in Belgium, about 100 percent, more than double its level in 1970. Sweden had the lowest debt ratio (at 44.2 percent) in 2015, approximately the same as in 1990. Average debt of this eight countries was near 27 percent in 1970 and higher by 60 percent in 2015 (86.4%).

### **3. Structure of Public Debt in the European Union Countries**

Eurozone debt crisis have necessitated the revival of the academic and policy debate on the impact of growing debt levels on economic growth. Most studies on relationship between public debt and growth, for example Reinhart and Rogoff (2010), Kumar and Woo (2010), Schclarek (2004), have found a negative impact of high public debt on long-term economic growth. Kramolišová and Spáčilová (2015) examined this relationship on the sample of 27 EU countries and also found negative relationship. Some studies were looking for a threshold over which additional debt has a negative impact on economic growth. Checherita and Rother (2010) investigated the relationship on the sample of 12 euro area countries and determined the threshold at about 90-100% debt-to-GDP ratio. Baum et al. (2013) found on same sample the threshold above 95%. Cecchetti et al. (2011) obtain a threshold for government debt at 85 % of GDP. Up to threshold, additional debt has a stimulating impact on growth, as found, for example, by Hsing (2017) for Poland, for which the current level of the debt-to-GDP is sustainable.

#### ***3.1 Analysis of Risks Arising from the Debt Structure***

The impact on the economy of the indebted countries has not only the amount of debt but also its structure. There are several macroeconomic reasons for attaching importance to the composition of government debt. The composition of government debt in terms of maturity, currency and investor base influences both a government's costs and the risks related to the rollover of outstanding government debt. Melecký and Melecký (2015) state that good government debt management reduces the country's vulnerability to financial crisis and financial risks. According to them, the debt management costs are usually high and limit the available sources for the other purpose. Quality debt management can minimise the costs in view of the risks related to the issuance of government debt.

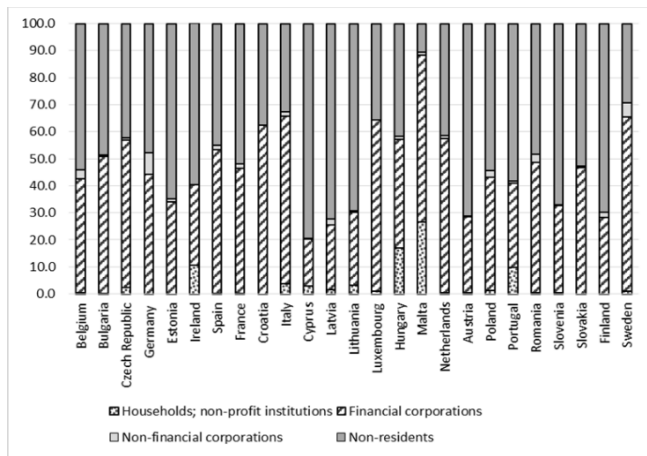

Murín (2017) studied the effects of three public debt decomposition – original maturity of debt instrument; currency which is used to issue debt and the residency of creditors – on economic growth. His results suggest that the most important shift seems to be from domestic to foreign creditors which is associated with the higher economic growth rates. Similar but not as strong effects, he obtained for the shift from domestic to foreign currency and for the shift from long term debt instruments to short term debt instruments.

Knowing who holds the debt is important for assessing whether debt flows involve a net transfer of external resources across countries and assess whether holders are likely to be subject to panic attack and lead to runs on a country's public debt. A large share of public debt in hands of non-residents may be a sign of confidence in well-performing economy. The currency of denomination is important for determining the risk of currency mismatches, and maturity is important for determining rollover and interest rate risk.

At the end of 2016, the debt share held by non-residents was significant for most of the countries but highly variable between countries. Among EU Members (see Figure 2), the share of public debt held by non-residents was highest in Cyprus (79%), followed by Latvia (72%), Austria (71%), Finland (70%) and Lithuania (69%). The lowest share has Malta – 10.5%. In

contrast, the largest proportion of debt held by the resident financial corporations sector countries for which data is available was recorded in Sweden (64%), Luxembourg (63%), Croatia, Italy and Malta (all 62%). In most countries, less than 10% of debt was held by the resident non-financial sectors (non-financial corporations, households and non-profit institutions serving households), with the noticeable exceptions of Malta (28%), Hungary (18%), Ireland and Portugal (both 11%).

**Figure 2: Government Gross Debt by Sector of Holder in EU-28, 2016, Percent**

Source: Eurostat (2018), author’s elaboration

A domestic currency denomination of debt protects country against exchange rate movement risks. The euro is the domestic currency for the euro area countries. In 2016, 100% of the stock of government debt was denominated in euro for Belgium, Estonia, Luxembourg and Finland. Another euro area countries, except Lithuania and Latvia, issued more than 90% of their debt in euro as domestic currency. The domestic currency is the major issuing currency also for some non-euro countries - Denmark (98.7 %), Sweden (90.6 %), Poland (72.8%), the Czech Republic (56.0 %) and Romania (50.5%). Only two countries issued more than 50 % of their debt in foreign currency: Bulgaria (80.5 %) and Croatia (76.5 %).

**Figure 3: Government Gross Debt by Financial Instrument in EU-28 and EA-19, 2016**

Source: Eurostat (2018), author’s calculations

Looking more closely at the composition of financial instruments in Figure 3 for the EU-28, 15.0% of the general government debt was made up by loans, 4.1% by currency and deposits, 80.9% was made up by debt securities at the end of 2016. In the euro area, public debt decomposed in financial instruments has similar structure (see Figure 3). For most of EU

Member States, the most used debt instrument remained debt securities. The smallest share of debt in securities has Estonia (11.1%), the highest share has Malta (93.3%), Czech Republic (90.8%) and United Kingdom (88.1%). The second most important instrument are loans, and this is particularly true for Estonia (86.6%), Greece, (80%) and Cyprus (67.3%). Significant loan to total debt ratios were also recorded for Luxembourg (39.8%), Portugal (35.5%) and Croatia (35.2%). Higher ratios of loans in Greece, Cyprus and Portugal are related to loans of EFSF, ESM and other international assistance.

Composition of debt in terms of financial instruments is related to debt maturity. As we can see in Figure 3, long-term securities, i.e. securities with initial maturity of over one year, represented 75.5% of government debt in European Union, while short-term securities accounted for 5.4% in 2016. The maturity composition of government debt affects the yield curve and hence the financing conditions of the private sector, with possible effects on overall economic activity. The maturity of debt also affects an ability to repay debt. Equiza-Goñi (2016) in his analysis suggests that extending debt maturity in 2013-2015 would result in lower debt ratios by 2022. A large share of short-term public debt indicates higher rollover risk. This risk exists for most EU countries except Bulgaria, the Czech Republic, Estonia, Latvia, Lithuania, Luxemburg, Poland and the Slovak Republic (< than 1% of debt in short-term securities). Hungary has the highest ratio of debt with short-term maturity (15.3%).

#### 4. Conclusion

A rising debt burden has implications for the economy in the shape of a greater amount of resource allocation towards debt servicing in the future. In order to meet debt servicing obligations, an extra burden is placed on limited government resources and may costs in the shape of foregone public investment or expenditure in other sectors of the economy. However, according to Vološin and Vološinová (2016), the current stage of development is characterized by the persistence of certain models of economic policy, even if they already do not provide adequate solutions to current problems. Also, more research needs to be undertaken in the field of public debt and its structure.

Hence, alongside the level of the debt ratio, analysis of the composition of government debt (debt maturity, residency of holders, currency denomination) is also warranted. According to our findings, the debt share held by non-residents was significant for most of the European Union countries; only two countries issued more than 50% of their debt in foreign currency and the most used debt instrument are long-term securities. Most European Union Members which have a large stock of long-term domestic currency debt hold by foreign holders are less vulnerable to financial crises. There is only one country with vulnerable structure of its debt (short-term maturity, foreign currency denomination, resident holders) – Romania.

### **Abstract**

*This scientific study reflects and investigates presented attitudes of political leaders of Slovak republic, that deal with the topic of migration in European medial context perceived by young voters (February 2018). We focus on the way this topic is presented in a European context by three topmost constitutional actors – president, prime minister and chairman of parliament. We investigated, by the method of semantic selection, the semantic maps of voters to political leaders/constitutional actors in relationship to the topic of migration and receiving of refugees. To mark the relationship of political representatives to the researched topic, we have chosen commonly known phrasemes, denoting character, personality and intellectual traits of a human being. The results of psychosemantic methods allow for detection of hidden, implicit meanings and help in this way to predict or correct voter's preferences.*

**Keywords:** migration, phrasemes, political communication, semantic maps, the European Union

**JEL Classification:** F02, F51, C90

### **1. Discursive Media Strategies on Migration in the European Context**

The aim of the present paper is to identify the social representation of the relation of political leaders in the Slovak Republic (President Andrej Kiska, Prime Minister Robert Fico, Head of Parliament Andrej Danko) and the political topic of security and migration in the EU context. Based on the results of qualitative analysis of the media discourse of the above political leaders in the period from July 2017 to January 2018 and the results of a modified semantic selection test, we are trying to identify the stance of the politicians in relation to the issue of migration in the semantic field of adolescents.

The issue of increasing migration is alive even after 3 years of international efforts to tackle and stabilize this socio-economic problem in the European context. In the years 2015-2016 there was an increasing “securitization” of the migrants on the part of the Slovak government, i.e. the influx of the refugees was primarily presented as a security risk regardless of their humanitarian needs and regardless of the fact that in the newly-approved Migration Policy of Slovak Republic with a perspective up to 2020 (2011) the government declared that “the Slovak Republic is in favor of an integration model based on bilateral adaptation in the integration process, in which the aliens contribute to shaping the common culture and the majority respects and supports their diversity”. The publicly presented views of the politicians on the social networks were mostly negative, as claims e.g. Chudžíková in the analysis of political and media discourse on the refugees in Slovakia (Hlinčíková and Mesežnikov, 2016, p. 95-111).

The politicians often used a combination of the so-called symbolic and realistic threats (Hlinčíková, Chudžíková, Gallová Kriglerová and Sekulová, 2016) – fear of the demise of what is known as the Slovak culture, fear of the economic threats, and after the events in Paris and Cologne, a perceived fear of death of the inhabitants of Slovakia. In addition to an exceptionally strong stereotypical patterning and homogenization of a large group of people only on the basis of their (purported) religion we can also observe a significant long-term dehumanisation of the refugees (Divinský, 2007; Vašečka, 2009; Žuborová and Borárosová, 2016). It is clear from the hitherto surveys of public opinion that a majority of Slovak citizens are mostly afraid of the refugees and do not support their arrival to Slovakia (Gažiová and Rapošová, 2016). The society still resonates with a vague and false perception of foreigners linked with the absence of perception of migration as a tool to counter the effects of a demographic and economic crisis (Vašečka, 2009, Spálová and Szabo, 2016). In the research conducted in September 2015 within the framework of the initiative Invitation to Humanity, the Slovak population showed low satisfaction with the participation and contribution of the Slovak Republic in the solution of the so-called refugee crisis. This corresponds with the findings of J. Androvičová (2015) who based on the approach of G. Campesi (2009) identified two key strategies in the criminalisation of the refugees resulting from the safety discourse. The first strategy can be labeled a “cultural threat” strategy, and it is built mainly on the differences in culture the migrants come from, and in highlighting the culturally contingent characteristics, which are often generally associated with negative activities (e.g. violent acts, crime). The second strategy is the so-called “security risk” strategy, which focuses on efforts to control crime through dividing the migrants into legal and illegal. We have also noted a significant shift in the rhetoric, manifesting itself as a transition from controlling to management of migration (Geiger and Péroud, 2010; Betts, 2008). The aim of migration management is not only to avoid the arrival of the migrants, but to regulate migration in such a way that it is “for the benefit of all”. The said dominant discursive strategies disseminated by the media have a negative impact on adopting the integration measures and creating an inclusive society (Gažiová and Rapošová, 2016).

In the recent period we marked a gradual reduction of the media coverage of security and migration, with the representatives of EU member states presenting themselves through seeking a uniform approach to the solution based on the defined aid, solidarity and regulation of the coming migrants. In view of the above, we wanted to map the perception of the relationship of Slovak constitutional politicians to migrants in the target group of adolescents.

## **2. Research Study - Relationship of the Political Elites to Migrants in the Semantic Area of University Students**

To identify the social representation of the relation of the Slovak political leaders/elites and the political topic of security and migration in the semantic area of university students, we used a psycho-semantic method – semantic selection test (hereinafter SST). When using SST, we focus on how the respondents view themselves and persons and things around in their semantic areas (Urbánek, 2003). In this area, every object has its place depending on its importance to the respondent. SST works with two types of elements, which will be called stimuli/terms and attributes/images. Both elements are “meaningfully charged” from the respondent's perspective. The respondent assigns attributes to the individual terms based on his/her own beliefs, emotions and associations.

In the original version of the SST, the attributes are rendered with 16 semantic pictures (house, flower, water, sun, lips, fish, eye, boat, moon, knife, bar, grave, spider web, snake, tree, worm). In this research study we present a modification of the SST, more specifically, its experimental

version using idioms and lexical phrases instead of the standard images, as they reflect human characteristics, nature and abilities (Habovštiaková and Krošlaková, 1996). Within the framework of the test structure, we replaced the attributes/images with phrasemes, which reflect human qualities and reflect the personal traits of an idealized concept a political leader, or traits that are undesirable and do not support the concept of a strong political brand. For this reason, we provisionally preselected phraseological antonyms with opposite meanings because they are connected by one semantic concept – in this case a property or ability (Ripka and Imrichová, 2003). The proposed approach is based on the assumption that phrasemes can be used to explicitly label the personality traits and abilities of political leaders. An important criterion is the referential nature of phrasemes in relation to the subject of research and the image of political leaders as perceived by the respondents. The selection was made from the lexical fields/fields of discourse in the Phraseological Dictionary (Habovštiaková and Krošlaková, 1996). Based on these fields of discourse we selected antonymous phrasemes for the respondent to select from, and we created a modified version of the test (the letter next to the phraseme represents the indication on Figure 1):

- 1) He wouldn't hurt a fly. (A)/A leopard cannot change its spots. (J)
- 2) He stands behind every word he says. (F)/He has a skeleton in the cupboard. (I)
- 3) He is a person of good repute. (K)/They pick on him. (B)
- 4) He can put two and two together. (M)/He has bats in the belfry. (E)
- 5) He is a recognized expert. (O)/He does not have a clue. (D)
- 6) He keeps his fingers on the pulse. (C)/He is buttoned-down. (G)
- 7) He speaks from the heart. (N)/He preaches water, but drinks wine. (P)
- 8) He is a yapper. (L)/He speaks words of wisdom. (H)

The usability of these phrasemes may be limited by their knowledge in the target group, therefore, we considered it appropriate to avoid phrasemes of a biblical origin, which might not be known by the youngest generation. A similar presumption was applied to the phrasemes from the Greek and Roman mythology because the respondents might have a limited knowledge of these units.

When setting the operational strategy to deal with the research problem, we used the theoretical concepts of medial discursive strategies and prior empirical knowledge on the subjective perception of the efficiency of use of the political leaders instead of the party (Spálová, 2015; Spálová and Szabo, 2017).

In the modified SST we have proposed to monitor the relationships (semantic maps) of the following terms:

- Terms with affinity to migration - in relation to select EU countries: Slovakia, Czech Republic, Germany, France, Russia,
- Reference terms with the generational factor: myself, grandfather, father
- Political/constitutional leaders and their use of personalization: Robert Fico, Andrej Danko, Andrej Kiska (the selection of the political leaders was based on the popularity and preferences of the selected politicians from the pre-election surveys (e.g. AKO, Polis, Focus) (TASR, pravda.sk, 2018)).

The research file consisted of the students in the field of marketing communication and advertising at the Faculty of Arts, Constantine the Philosopher University in Nitra in January 2018. The research was attended by 77 respondents – 18 men and 59 women.

### 3. Results

We used correspondence analysis to process the statistical data from the Semantic Selection Test. The closer the points on the chart, the higher the similarity between the corresponding categories. It is also possible to interpret groups of similar categories in relation to the position of the points relative to the main axes. The justification for the correspondence analysis method was examined on the basis of the result  $\chi^2$  - independence test. We rejected the null hypothesis on independence between the stimuli terms and phrasemes with the significance level less than 0,001 and we adopted an alternative hypothesis: the stimulation terms and phrasemes are dependent. Ten dimensions were extracted in the correspondence analysis. For a more appropriate visual representation, we will only work with two dimensions. The first dimension contributes with a value of 0.163, which represents an inertia of 65%, the second dimension contributes with a value of 0.03, which represents an inertia of 12%, for a total inertia of 77%. The correlation between the two extracted dimensions is close to zero ( $r = 0.096$ ).

**Figure 1: Perception of the Slovak Political Leaders/Elites to Migration Evaluated by Correspondence Analysis (Complete Set)**

Source: own elaboration (2017)

The reference term *myself* is in the quadrant of positive identification together with the generational overlaps, and it stands close to the terms *father* and *grandfather*. This quadrant is saturated by phrasemes *He stands behind every word he says*, *He wouldn't hurt a fly* and *He speaks from the heart*. We have observed a more desirable/ideal self-concept of the adolescents, i.e. what I would like to be; and these results indicate a greater tolerance of the migrants in the younger generation but at the same time stand contrary to the findings regarding the negative attitude to migrants in the Slovak population (Vašečka, 2009; Euractiv.sk, 2017).

Positive anchoring in relation to migrants is seen in the terms *Andrej Kiska* and *France*. The following phrasemes are associated with these terms: *He keeps his fingers on the pulse*, *He is*

*a person of good repute, He speaks words of wisdom, He can put two and two together.* The phraseme *He is a recognized expert* is in a close quadrant, but its nearest term is Andrej Kiska. Andrej Kiska speaks neutral to positive in the context of migration. According to his statements on the Facebook profile (during the observed period between July 2017 and January 2018), he views migration as a current EU problem along with security, climate change, all of which the country cannot deal with separately, but only in cooperation with other countries, particularly with the EU countries (October 23, 2017). In general, he calls for tolerance, solidarity and humanity. On December 19, 2017, right before Christmas, Kiska published a write-up on the dinner with Assyrian Christians who immigrated to Slovakia because of the Iraq war. Kiska did not advocate directly for receiving the refugees, but presented the family of Assyrian Christians as hardworking, good and diligent people. The neighbors first did not trust them, but later developed good relations with them (about trust see e.g. Fichnová, Wojciechowski and Mikuláš, 2018). Kiska tried to point out the prejudice against migrants because they also include decent people who are fleeing from war. This position corresponds with the migration policy in some EU countries. For example, France prefers the assimilation model to the discriminatory model – “...expects that the foreigners fully drop their native language and cultural & social characteristics and quickly assimilate into the majority society in return for a speedy acquisition of citizenship and the rights & duties it entails” (Nová, 2016, p. 674).

The third quadrant is anchored by the following EU countries: *Germany, Slovakia and the Czech Republic*. In relation to migrants, the countries are associated on the adolescent semantic map in conjunction with the following phrasemes: *He has a skeleton in the cupboard. They pick on him. He is buttoned down.* In contrast with the first quadrant, we can see the critical approach of adolescents to migration policy reflecting the mistrust in the solution of the migration issues by the political representatives of the countries concerned. Germany has welcomed the highest number of refugees (approximately 1 million). “The current disaster faced by refugees and forced-migrants in the aftermath of the Arab Spring is a dreadful illustration of persistent ambivalences: The Federal Republic, in the post-Nazi era and the European Union from its very inception, proclaim allegiance to human and citizens' rights, which serve, in ones and the same time to promulgate the promise of inclusion and equality, and as instruments of securitization and exclusion” (Banai and Kreide, 2017, p. 903). As a matter of comparison, the Czech Republic has taken a minimum amount of refugees, but the migration is resonating equally strong. „The Czech Republic has also begun to discuss its national interests, drawing on several conflictual moments in Czech history, at the moment of deepening the European integration in the late 1990s. ... The specific historical development including post-war national homogenization influenced also discussion about immigration policy on the national level. For the majority of the inhabitants of the EU European identity does not represent a strong enough identification. One of the consequences thus seems to be the rise of nationalistic movements which list the protection of a supposedly endangered national identity as the main goal of their activities“ (Nenička, 2016, p. 662). Kohoutek (2013, p. 106) argues that based on the current available data, more than a threat, immigration has become a securitized issue.

The most salient negative connotations are anchored in the fourth quadrant, and they include the explicitly negative phrasemes: *He preaches water, but drinks wine. He does not have a clue. He has bats in the belfry. A leopard cannot change its spots. He is a yapper.* associated with the political elites *Robert Fico* and *Andrej Danko* and reflect the negative perception of the adolescents. The said is also indicated by the perceived populism, corruption, lack of competence, and manipulation in the political marketing of Slovak political elites. On his Facebook profile (monitored in the period July 2017 to January 2018), Robert Fico regularly informed about the G4 summits, and expressly dismissed the compulsory quotas and the

creation of uniform Muslim communities in Slovakia (January 26, 2018). He stressed the joint decisions of the EU countries and notional overlaps. In the write-up about the EU and Africa summit, he once again stood up against migration and pointed out that the problem must be addressed directly in the country of origin, and the role of the EU is to help these countries at home (December 2, 2017). In Fico's opinion, a substantial part of migration is economic-based (January 26, 2018). He addressed this issue in a write-up titled "Slovak work for Slovaks" - "I do not want Slovakia to end up like Brussels – full of immigrants from foreign countries. I want that work is first and foremost given to the Slovaks who can increase their living standards." January 23, 2018). Migration was one of his main topics in the 2016 election campaign although the refugees did not pass through Slovakia and we only adopted a limited amount of migrants (Onderčanin, 2017). Fico also claimed that the migrants who came to Greece and Italy did not want to come to and stay in Slovakia. For Andrej Danko, the issue of migration was interesting in the later periods, e.g. on June 10, 2017 he issued a warning that Slovakia would be swept by thousands of migrants and it must implement a system of protection, e.g. compulsory military service, because of the coming "natural disasters" (SITA, 2017). In 2016 he often talked about the planned prohibition of burkas, about the failure of the EU in the area of security – particularly in the context of the Berlin attacks. Currently, Andrej Danko only rarely expresses his views on migration.

#### 4. Conclusion

The aim of the present paper was to identify the social representation of the relation of political leaders in the Slovak Republic (President Andrej Kiska, Prime Minister Robert Fico, Head of Parliament Andrej Danko) and the political topic of security and migration in the EU context using a modified semantic selection test. The semantic maps of adolescents reflect the significantly negative associations of the political elites in the Slovak Republic with the exception of the President of the Slovak Republic Andrej Kiska and the EU countries – Slovakia, Czech Republic and Germany, with the exception of France.

The results of this semantic selection test were complemented by a qualitative analysis of the statements made by the politicians on their official Facebook profiles. We followed their media discourse primarily in the period from July 2017 to January 2018. Based on the analysis of Fico's media discourse, his statements on migration can be seen in the context of the joint European solutions. "Several authors (e.g. Geiger and Pécoud 2010; Betts 2008) noted a major turnover in the migration discourse. They characterize it as a transition from migration control to migration management. In their view, the promotion of the so-called migration management is a split from the specifically defined and safety-oriented migration policy. The aim of migration management is not only to avoid the arrival of migrants, but to regulate migration in such a way that it is 'for the benefit of all' " (Androvičová, 2015, p. 335). Here lies the main difference between the official policy toward the EU and the statements to local general public stemming from the national policy. Fico's statements developed the migrant discourse as a threat to national security, which resulted in Fico's efforts and emphasis on dealing with migration and refugees in the European context since, in his view, the danger applies to all European countries, as well as the global migration discourse. "Major findings highlight the lack of symbolisms inside institutions to raise their standards and place European Union as identity superpower, even though they take significant initiatives to use the refugees/migrants crisis, with one and only purpose: Strengthening social relations between the state-members of the Union" (Remanda, 2017, p. 153). The discourse of fear is also strong in other European countries, and it affects the law, order, and religious and cultural differences (Bolonyai and Campolong, 2017), which requires a response with specific solutions (Stevens, 2017).

Andrej Danko made only a few statements on migration policy in the second half of 2017, but in the preceding period he used a national security concerns discourse – just like Fico.

Kiska addressed the topic of migration in a neutral manner, he took it as a current problem in the European Union along with security and climate change, which the country cannot battle separately, but only in cooperation with other countries, particularly those from the EU. Similarly to Robert Fico, he pointed that safety is a priority of the state. The migration phenomenon coupled with the negative consequences of the economic crisis has led to the strengthening of racist, xenophobic and intolerant ideas, hoisted by the parties of the European extreme right handgrip found in sectors of the population (Busutil and Marquez, 2017). In contrast, he calls for tolerance and, using the example of the Assyrian Christian family, develops the discourse of migrants being victims, "having no other choice", and being a benefit.

The media play a key role in the creation of opinions and attitudes toward social issues in the young generation (Štrbová, 2016). "Media still are the main means of information with regards to distant topics (the refugee crisis included) and facilitators of people's access to social reality." (Buturoiu, Stefanita and Corbu, 2017, p. 20). The results indicated a link between the anti-migration media comments by Robert Fico and Andrej Danko and their negative perception by the adolescent youth, and the neutral statements by President Andrej Kiska, and his implicit pro-immigration attitudes were perceived positively by the adolescent youth.

### **Abstract**

*Openness to trade, investment and even the movement of people is vital for prosperity, peace and individual freedom. And there have been few better moments in history to reconfirm the role of trade as central to global growth, job creation and development. Today's economic circumstances are full of challenges. China has come a long way since the 1978 election of President Deng Xiaoping heralded a new era of market-oriented reforms. From 1980 to 2010, its economy grew 18-fold, averaging 10 percent a year. It progressed from low-income to upper-middle income country status, lifting hundreds of millions out of poverty: by 2011 just 6 percent of people were in extreme poverty, compared with 61 percent in 1990. Recent developments – including the weakening of the yuan, the stock market crash, rapid credit growth, and a stalling property market – have cast some doubt on China's economic prospects. Yet a hard landing of the Chinese economy still seems unlikely. China has the opportunity to be a global leader in a number of important areas that will be cornerstones of global growth in the next decades and this is also challenge as well as threat for the United States, Japan and especially the European Union Member States.*

### **1. Introduction**

Openness to trade, investment and even the movement of people is vital for prosperity, peace and individual freedom. And there have been few better moments in history to reconfirm the role of trade as central to global growth, job creation and development. Today's economic circumstances are full of challenges. Global growth remains fragile after the 2008-2009 crisis, with few bright spots in the global economy. Potential output growth has declined in recent years across developed and developing economies owing to structural factors that led to lower productivity growth (IMF, 2015). Trade growth is weaker than at any time in the past two decades. In some quarters there is a sense that the financial crisis presents a case to roll back much of the deep integration that began after the Second World War and took hold rapidly since the 1980s. Global opinion shows views on openness are uneven. A September 2014 Pew poll indicated that while there is strong support for trade in developing countries, the picture is more mixed in advanced economies, particularly in perceptions of employment and wage effects (Pew Research Center, 2014). Yet it is these advanced economies that have historically been the drivers of a more globally integrated world, leading eventually to a multipolar world with changing global political-economic relations.

At the same time, there are signs of new energy in global integration. Negotiations have intensified in several major groupings, including the Trans Pacific Partnership, the Transatlantic Trade and Investment Partnership between the European Union and the United States, the Regional Comprehensive Economic Partnership (RCEP) in Asia, the Pacific Alliance in Latin America and the Tripartite Free Trade Agreement in Africa. Since the December 2013 Bali Ministerial Conference, the World Trade Organization (WTO) has a new agreement on trade facilitation. When viewed within a longer perspective, this energy is not surprising, forming part of a long trend towards more closely interlinked global markets. With the move to a more multipolar global economy, more players have joined the game. Since 1970, the share of developing countries in global trade flows has more than doubled, now making up close to 40% of world trade. An almost fourfold increase has brought them to half of the share in global foreign direct investment flows; and their share in global GDP has doubled from 15 % to 30 % (WEF, 2015, p. 4).

These developments have also intensified competition in global markets, which, in turn, implies a greater need to be competitive to generate additional market opportunities and economic links in the presence of many more participants vying for the same space. China has the opportunity to be a global leader in a number of important areas that will be cornerstones of global growth in the next decades and this is also challenge as well as threat for the United States, Japan and especially the European Union Member States (Fojtíková, 2013). These facts involves several questions to be solved: Against this backdrop, what can openness to trade and investment contribute to a sustained global recovery? How can the potential gains through global value chains be harnessed? How do countries increase their competitiveness to take better advantage of the global economy?

## **2. Relations of International Trade and Competitiveness**

Since the global financial crisis, policy-makers have focused mainly on macroeconomic policies, emphasizing fiscal and monetary stimulus as well as financial reregulation. This is not the place to argue the pros and cons of such policies. However, such a focus has come at the expense of attention to structural reforms to address sluggish productivity within economies. Microeconomic constraints to growth – distortions in product and factor markets, education, skills, and infrastructure – have not been sufficiently addressed. This is where the competitiveness agenda kicks in. Trade and competitiveness are intimately connected. Competitiveness can be defined as the set of factors – policies, institutions, strategies and processes – that determine the level of sustainable productivity of an economy, be it the world, a continent (or macro region), nation, region or even a city (WEF, 2014). Competitiveness centres on productivity – the efficiency with which an economy uses available inputs to produce outputs. It determines the rate of return on investments, which fundamentally drives economic growth. Openness to the world – through trade, investment and the movement of people – is crucial to competitiveness. But openness on its own has its limits. To reap its benefits fully, it must be combined with productivity-enhancing reforms at home. This is the rationale for pursuing reforms to advance a twin focus on trade and competitiveness.

The historical record is clear: no country has developed successfully in modern times without harnessing economic openness for its national development. Of course, the paths taken by individual countries have varied greatly. Of the 13 countries with sustained growth trajectories surveyed in the landmark 2009 Growth Commission report, each took different pathways and had different mixes of economic activities (Commission on Growth Report, 2009). However, the common thread between the countries that have grown successfully is that they have exploited the potential offered by openness to create new economic opportunities for their people. They have also harnessed global economic forces to drive greater efficiency,

innovation and productivity in their own economies. In other words, they have not only looked within for the elements needed to bring long-term prosperity but also have looked outside their borders and made the most of what economic integration can offer (WEF, 2015).

Although openness comes with risks and costs, experience shows that when managed effectively these are short-term and far outweighed by the long-term gains. The benefits of trade and investment integration can be thought of in two ways, both of which are well known. First, they help create new economic opportunities by increasing the size of the market available to domestic firms as well as driving potential value chains with which they could link up their own production. Second, they drive productivity and innovation by exposing firms to international competition, expertise and technology. Through these two channels, trade makes a significant contribution to poverty reduction, helping to unleash the potential of the private sector to create jobs. It is wages earned through jobs that provide the key means for improving welfare: countries such as China and Vietnam, following in the footsteps of previous generations of East Asian Tigers, have been able to lift hundreds of millions out of poverty through steady growth in the wages earned by workers in fast-growing economies (World Bank Group and World Trade Organization, 2015). And in advanced economies, employment and wage levels have become a key test of the effectiveness of economic growth in delivering widespread benefits.

Along with its economic benefits, openness to the global economy brings geopolitical benefits. Although the world is going through a turbulent phase geopolitically – from the Middle East, to Ukraine, to maritime East Asia – there is no doubt that the close ties brought about through ever deeper economic integration have contributed greatly to overall peace and stability since the Second World War. At the regional level, growing understanding of how integration among neighbours can deliver long-term economic gains has led to increasingly close cooperation. In East Asia, for example, although tensions occasionally surface, economic dependence through regional production networks, uniting the ASEAN countries with northeast Asia (China, Hong Kong, Japan, Taiwan and the Republic of Korea) makes all out conflict today highly costly and much less likely (Baldwin 2011, 2014; Kovářová, 2016).

### **3. Why Openness Still Matters? Beyond Openness – the Need for Competitiveness**

Openness is an indispensable enabler of growth, job creation and development. But openness alone does not lead to success. The competitiveness of economies in an integrated world determines how well they convert the potential created by access to global markets into opportunities for their firms, farms and people. What does this entail? First up are policies and regulations that affect the business climate. Stable macroeconomic conditions are critical, as are well-functioning markets for the key inputs in any economy – land, capital and labour. The level of competition in the domestic economy is an important determinant of how well its firms will compete with the rest of the world. Innovation capacities can give a competitive edge to firms; as can the capacity to bring small and medium sized enterprises (SMEs) from their formative stages to businesses with the ability to compete in a global market.

“Institutions” are as important as “policies”. These include efficient public administration, timely decision-making and the rule of law – all aspects of “good governance”. Also important is “hard” infrastructure – transport (airports, ports, roads and railways), communications, energy and logistics, along with “soft” infrastructure, including education and skills. Finally, an understanding of how policies and institutions interact to affect competitiveness, both at the level of the economy overall and at the level of particular industries, is important.

Competitiveness is often presented as a relative concept (i.e. an economy is more competitive than another one), which leads many to see competitiveness policy as a zero-sum game. In reality, improving competitiveness simply means to create conditions that allow an economy to allocate scarce resources where opportunities arise as external and internal conditions change. At the global and continental (or macro-regional) level, uncooperative national policies are a primary constraint to competitiveness. And as production increasingly transcends borders, the spill over effects of domestic policies multiply in number and size. Improving competitiveness is as much a collective effort as an individual one. Countries that want to boost the productivity of their economies need to cooperate to have functioning and up-to-date supranational institutions and frameworks.

Indeed, the content of most economic integration agreements today is a striking demonstration of the wide range of policies that shape a country's interaction with the global economy. "Trade agreements" stopped being only about tariffs and market access rules years ago. The mega-regional deals currently under negotiation will cover economic activities and areas of regulation that were once thought well beyond the purview of international negotiations. These include rules on investment, services, intellectual property, public procurement, state-owned enterprises, coherence of domestic regulations, competition policy transparency, SMEs, environmental regulation and labour standards (WEF, 2015).

It is striking that attention on these competitiveness policies is focused not only at the national and international level. With cities contributing 80 % of the world's GDP – despite housing just over a half of the world's population – a growing focus on the drivers of competitiveness at the city and subnational level is unsurprising. Attracting international trade, investment and mobile talent, as well as finding productive niches in Global Value Chains (GVCs), are now critical to city and sub-national competitiveness. The increasing spread of GVCs and skills present opportunities for countries to connect to high value-added parts of production processes without having to develop entire industries within their borders. GVCs have also brought into sharper focus the importance of trade facilitation, investment and "behind-the-border" policies for competitiveness. Engagement between governments at the city and sub-national level, the private sector and other stakeholders can reshape the environment in which business operates and significantly boost prosperity.

#### **4. China's New Normal**

Ten years ago, the global financial crisis interrupted a period of sustained economic growth dating back to the 1960s. Since then, despite unorthodox monetary policy and fiscal stimulus packages, advanced economies have experienced prolonged comparatively sluggish growth. In emerging markets, the impact of the global financial crisis was lessened in part by interest rate differentials, with advanced economies fuelling capital inflows in the form of foreign direct investment, the commodity super boom, and – related to this – the rapid growth of China. China has come a long way since the 1978 election of President Deng Xiaoping heralded a new era of market-oriented reforms. From 1980 to 2010, its economy grew 18-fold, averaging 10 percent a year. It progressed from low-income to upper-middle income country status, lifting hundreds of millions out of poverty: by 2011 just 6 percent of people were in extreme poverty, compared with 61 percent in 1990 (World Bank Group and World Trade Organization, 2015).

Recent developments – including the weakening of the yuan, the stock market crash, rapid credit growth, and a stalling property market – have cast some doubt on China's economic prospects. Yet a hard landing of the Chinese economy still seems unlikely, for three reasons. First, as the Global Competitiveness Index (GCI) shows, China possesses strong economic foundations. The country ranks 27th out of 137 economies in the 2017-2018 edition (WEF,

2017). China has achieved near universal primary education and high levels of public health, invested massively in transport and energy infrastructure, and ensured a relatively stable macroeconomic environment. These successes not only have contributed to China's emergence as a manufacturing hub, they also represent assets on which to build. China's advantages are not shared by many neighbouring economies at a similar stage of development, as shown by Figure 1.

**Figure 1: China in the 12 Pillars of the GCI (Score 1-7)**

Source: WEF, 2017, p. 90

China (27th) has gained one place as a result of steady, albeit incremental, improvements to its overall competitiveness score. Since last year, China has made progress in all pillars except its macroeconomic environment and infrastructure. A decline in the former is explained by a worsening of the government budget deficit, which has been slightly higher than the expected target for 2016. The score for the infrastructure pillar decreases for the second year in a row, the result in part of a decline in the quality of port infrastructure and the reliability of electricity supply as perceived by the business community. The largest gains are observed in technological readiness, owing to higher ICT penetration and the extent to which foreign direct investments have been bringing new technologies to China. Despite the remarkable progress already made, further improvement on this front would foster the growth of emerging digital industries and create the conditions necessary to kick-start new ones. Other significant advances have been made in the goods market efficiency pillar as a result of a slight reduction in the number of procedures for starting a business compared to last year.

Second, an eventual slowdown was inevitable, predictable, and entirely normal, given China's impressive growth trajectory over the past two decades. WEF also compares China's annual real growth rate since 1980 to the GDP-weighted average growth rate of other countries in the income group to which it belonged in each year. Since 1991, China has grown faster than its peers every year. For several years in the 1990s, the differential was almost 10 percentage

points. Since achieving upper-middle-income status in 2010, the differential has been around 5 percentage points.

Third, even though it has not yet abandoned the official 7 percent target, there are signs that the government has been preparing for the economy’s new phase and has been recalibrating its growth objectives from the quantitative to the qualitative. The 12th five-year plan, adopted in 2011 and covering 2010–15, had called for a rebalancing of the economy; more recently, President Xi referred to a “new normal” under which growth will be lower.

Even though the economy is unlikely to experience a hard landing, the challenges and downside risks are many. Under the new normal, productivity gains will be harder to achieve. This is reflected in China’s stagnation in the GCI rankings for the past four years. The drivers that fuelled China’s growth—investment, low wages, urbanization—are yielding diminishing returns or even vanishing, as shown by the downward trend of overall productivity since 2007. Future gains will have to come through more market-oriented reforms that tackle remaining distortions, controls, and rigidities across the economy and that enable more efficient use of factors of production.

The GCI points to the structural weaknesses of China’s financial sector: it ranks 78th for the soundness of its banks, which have accumulated many non-performing loans. The sector is dominated by large state-owned banks, and credit flows more to state-owned enterprises or large corporations with connections than to small- and medium-sized enterprises: access to finance is rated as the second most problematic factor for doing business in China (Figure 2). A rank of 46th on goods market efficiency highlights the need to create a level playing field in non-strategic economic sectors by reforming state-owned enterprises and subjecting them to fair domestic and foreign competition, and by tackling corruption and bureaucracy. Moving beyond market efficiency, the list of the most problematic factors for doing business in China is topped by its lack of capacity to innovate, which has become a growing concern in recent years (Figure 2). Evolving from a manufacturing-based economy to an innovation powerhouse for design and R&D requires a holistic approach to the innovation ecosystem, including nurturing talent (China ranks 47th in higher education and training) and technological readiness (ranking 73th; technology is still far from universally available, let alone used).

**Figure 2: The Most Problematic Factors for Doing Business in China**

Source: WEF, 2017, p. 90

The progress that China has already made in rebalancing its economy suggests its capacity to identify and rectify weaknesses in its growth model. Since 2005, the relative importance of manufacturing in China's economy has been declining steadily, and services now account for a bigger share of GDP. Meanwhile, a fledgling social safety net consisting of a healthcare and pension system, along with rising incomes and lower exports, have initiated a rebalancing of demand toward domestic consumption. China's "new normal" will bring further challenges in improving productivity, but its strong performance elsewhere in the GCI indicates that the country is well positioned to meet them.

## **5. Conclusion**

Trade and competitiveness are intimately connected. As demonstrated by the East Asian "miracle economies" (Hong Kong SAR, the Republic of Korea, Singapore, and Taiwan), trade and investment integration can improve competitiveness through two channels: first, by increasing the size of the market available to domestic firms; and second, by driving productivity and innovation by exposing firms to international competition, expertise, and technology. No country has developed successfully in modern times without opening its economy to international trade, investment, and the movement of people across borders. Conversely, it is the competitiveness of economies – the level of productivity of continents, nations, subnational regions, and even cities – that determines how well they translate openness to trade and investment into opportunities for their firms, farms, and people. Trade and competitiveness come together in GVCs. Trade no longer means merely goods crossing borders; rather it is the international, interconnected flow of goods, services, investment, people, and ideas along a value chain. Production stages that previously took place in a single factory, or in a single country, are now dispersed across many factories in many countries. GVCs are the key drivers of employment, productivity, and growth in international trade. They create niches for developing countries to industrialize faster and better, and they enable developed countries to specialize in higher-value production in goods and services, thus improving wages and consumer choice. Taking advantage of GVCs demands more than keeping borders open to trade and investment: a whole host of domestic non-tariff and regulatory barriers also need to be removed as well as a welcoming business climate provided. Unilateral measures can help countries take advantage of GVCs, but they work best when they are locked in by international agreements such as those negotiated by the World Trade Organization, bilateral investment treaties, and regional trade agreements (WEF, 2015).

Openness has non-economic benefits, too. Wider and deeper cross-border economic integration has contributed greatly to overall peace and stability since World War II. It has increased individuals' freedom to produce and consume in daily life, widening the life choices and chances of large numbers of ordinary people. However, openness and the links between trade and competitiveness have fallen off the agenda in recent years. Since the 2008-2009 crisis, policymakers have been in fire-fighting mode, focusing on fiscal and monetary macroeconomic stimulus and financial reregulation. This has arguably come at the expense of supply-side issues and structural reforms needed to address sluggish productivity growth. Supply-side constraints to growth – distortions in product and factor markets, education, skills, and infrastructure – have not been sufficiently addressed; if anything, market distortions have increased since the crisis, undermining competitiveness. And although protectionism has not surged, there is evidence of creeping protectionism, especially with increasing non-tariff barriers to trade. Global trade growth is weaker than at any time in the last two decades. Strengthening both global openness and domestic competitiveness has never been more important. To revive sluggish productivity and tap new sources of growth, innovation, job creation, and development, a trade-and-competitiveness agenda should be a priority for policymakers around the world.

## **Social Inequalities within the European Union: How to Efficiently Measure the Implementation of the Europe 2020 Strategy Goals?**

**Michaela Staníčková**

VŠB-Technical University of Ostrava

Faculty of Economics, Department of European Integration

Sokolská třída 33, 702 00 Ostrava 1, Czech Republic

e-mail: michaela.stanickova@vsb.cz

### **Abstract**

*Economic crisis hit all the European Union Member States hard, the impact of crisis varied considerably. The low growth performance in the EU has increased concerns regarding an increasing wage dispersion, income inequality at large, and social exclusion in line with poverty. Inequality should be seen as a cornerstone of both sustainable and inclusive growth under the Europe 2020 Strategy. Social inequality in the EU is a very real problem that hampers sustainable economic growth. The purpose of this paper is to introduce evaluation of social development convergence and divergence trend between EU28 Member States in the context of the Europe 2020 Strategy and to review the relevant approaches to evaluation of territorial development (especially the EU case) based on composite indices. The paper gives an outline of the issues of labour market and income disparities and poverty. Policy-makers must be clear about what social objectives they are aiming to achieve, therefore special attention is paid to headline national goals of the Europe 2020 Strategy. Measurement of territorial progress with regards to achieving the developmental potential plays a crucial role in improving the prosperity and quality of life in any territories.*

### **1. Introduction**

Improving the standard of living and quality of life for societies has undoubtedly become one of the most important objectives across the globe. The achievement of this developmental objective is complex and difficult issue. Preceding views on the attainment of higher output as a means to its achievement have faded away on the basis of higher global inequalities and incidences of poverty, notwithstanding the presence of strong economic performances. Greater emphasis has thus been directed towards the collective improvement of social, cultural and economic aspects of areas, resp. multidimensional aspects and endowment of territories. Economic development in this regard has been viewed as an important process which asserts an enhancement of both qualitative and quantitative features in territories contributing to higher levels of prosperity (Meyer et al., 2016). However, as a multidimensional process, the measurement of the progress which societies have made in their developmental efforts, has proven to be difficult but also very popular.

The European Union (EU) faces many challenges. On the global stage, the EU has to speak with one voice to counter a plethora of political, military and economic crises. Internally, it needs to foster cohesion in spite of the many events that threaten the EU at its core. In this context, do social issues matter at all? If we look at the EU evolution over the past decades,

substantial progress has been made in terms of building an internal market and an economic and monetary union, albeit not without problems, as the 2008 crisis has shown. It looks actually, as if the EU and its Member States were mostly thinking in economic terms, hoping that economic solutions will fix all social problems at once. To negate the importance of social issues is to undermine the EU foundations (Allmendinger and Driesch, 2014). Many politicians and economists believe that economic growth replaces or diminishes the need for social policies. However, the EU growth over the last decades has been accompanied by increase in inequalities in many countries. Inequalities threaten social cohesion and they threaten growth.

If such concerns are correct, it is essential not only to build institutional structures for European social union but also to map social inequalities in the EU. The low growth performance in the EU over the recent decades has increased concerns regarding an increasing economic dispersion, income inequality at large, and social exclusion. Recent research works has stimulated fierce debate on inequality among academics and policy makers. The recent economic crisis revealed many of the weaknesses of the current European economic policy, not least at the level of its fiscal policy, monetary policy, industrial policy, and social policy, and its inability to address problems related to inequality. Inequalities in the EU have been the object of extensive research over the last decade. Several factors can explain this widespread interest; especially the revival of growth theory was contemporaneous with a growing empirical literature on economic convergence (Sala-i-Martin, 2006).

The level of social inequalities belongs to important indicators influencing the socio-economic development and other processes taking place in the social and economic realm. Facilitating rational income distribution and reducing poverty are mentioned among the main goals of public policy. It should be mentioned that such multidimensional phenomena as income disparity and poverty might be analysed from many different perspectives, including the national and international, also within the EU. Striving for fairness in economic development is crucial in order for societies to be stable and citizens not to feel disenchanting. The economic crisis has put inequalities high on the political agenda, and made this an issue of serious public concern. There is an increasing recognition that social policy can reduce inequality and poverty while simultaneously improving the economic functioning of the country as reflected in the idea of inclusive growth in the EU's Europe 2020 strategy, with references to a high-employment economy delivering economic, social, and territorial cohesion in which benefits of growth and jobs are widely shared. In view of the current debate and the literature review, the objectives of this study focus on the following key issue, i.e. to describe the recent evolution of inequalities and dispersion across the EU Member States using different definitions of social inequality measures in relation to the Europe 2020 Strategy, i.e. the main research question is how to efficiently measure the success implementation of the Europe 2020 Strategy goals?

## **2. Relations of Competitiveness and Inequalities**

The multidimensional nature of quality and inequality issues and the disparate social policy priorities of nations and other regions in addressing these calls for a reconciliatory performance evaluation framework. The competitiveness and welfare level of the people of any country is clearly related to the performance of its potential economic growth. A keen interest in economic growth or productivity growth is the objective of economic policies. The competitiveness and welfare level of people of any country is clearly related to the performance of its potential economic growth. The keen interest in economic growth or productivity growth is the objectives of economic policies. Therefore, the economic performance of countries and the world as a whole has formed the subject matter of numerous studies over the last decades. Academics and policy makers are concerned with the evolution

of inequality and its negative effect on development, see Rajan (2010), Stiglitz (2009) or Krugman (2008). This is also the case of the EU. Nevertheless, the differences between the EU Member States are enormous. Small, rich countries, such as Luxembourg, contrast sharply with big, poor ones, such as Romania. Despite this, many indicators are published which refer to the EU as a whole, including measures of socio-economic inequalities and with the time. The recent economic crisis revealed many of the weaknesses of the current European economic policy, not least at the level of its fiscal policy, monetary policy, industrial policy, and social policy, and its inability to address problems related to inequality. The current Europe 2020 Strategy aims achieving an inclusive economic growth, benefitting the largest possible number of people, while other international institutions are also fully concerned with inequality issues. The European Council approved the Europe 2020 strategy, an economic growth and well-being improvement plan for the EU in the ensuing decade. The strategy includes five interrelated headline targets to be achieved by the year 2020, encompassing employment, innovation, education, poverty and social inclusion, and climate/energy. Inequality should be seen as a cornerstone of sustainable and inclusive growth.

For the EU, the deepening social inequalities represent a very real threat to the well-being of many EU citizens, with so many being left behind as the overall European prosperity increases. Nevertheless, the differences between the EU Member States are enormous, as mentioned above. Small rich countries, such as Luxembourg, contrast sharply with big poor ones, such as Romania. Despite this, many indicators are published which refer to the EU as a whole, including the measures of socio-economic inequalities in time. The recent economic crisis revealed many of the weaknesses of the current European economic policy, not least at the level of its fiscal policy, monetary policy, industrial policy and social policy, and its inability to address problems related to inequality. Inequality is a key problem which the EU is facing, and it has significant impacts not only on human well-being, but also on economic performance. In order to address this problem properly, there is a need for substantial changes in economic theory, and in the empirical measurement of inequality. The effectiveness of the European convergence policy can also be improved by a clever choice of country-specific social activities and significant economic growth. Inequality can have many dimensions. Economists are concerned specifically with the economic or monetarily measurable dimension related to individual or household income and consumption. However, this is just one perspective, as inequality can also be linked to inequality in skills, education, opportunities, happiness, health, life expectancy, welfare, assets and social mobility. Inequality can be defined and measured as a specific resource distributed across the whole society; while economic inequality means primarily differences in earnings and incomes, social inequality relates to differences in access to social commodities including education and healthcare, but also social and institutional networks. While the EU has a clear role and competences in reducing inequality, reducing inequality at the national level within the EU countries is still a precondition for reducing inequality at the multinational level of the EU as a whole.

In this context, Staničková (2017) also raised the question about influencing the aspects of social quality and inequality – do social issues matter at all? If we look at the EU evolution over the past decades, substantial progress has been made in terms of building an internal market and an economic and monetary union, albeit not without problems, as the 2008 crisis has shown. In fact, it looks as if the EU and its Member States were mostly thinking in economic terms, hoping that economic solutions will fix all social problems at once. To negate the importance of social issues is to undermine the EU foundations (Allmendinger and Driesch, 2014). Many politicians and economists believe that economic growth replaces or diminishes the need for social policies. However, the EU growth over the last decades has been

accompanied by an increase in inequalities in many countries. Inequalities threaten social cohesion and growth.

Inequality is a key problem facing the EU, and it has significant impacts not only on human well-being, but also on economic performance. In order to address this problem properly, there is the need for substantial changes in economic theory, and in the empirical measurement of inequality. The effectiveness of European convergence policy can also be improved by clever choice of the country-specific social activities and significant economic growth. Inequality can have many dimensions. Economists are concerned specifically with the economics or monetarily measurable dimension related to individual or household income and consumption. However, this is just one perspective and inequality can be linked to inequality in skills, education, opportunities, happiness, health, life expectancy, welfare, assets and social mobility. The inequality can be defined and measured as specific resource is distributed across the whole society, while economic inequality means primarily differences in earnings and incomes, social inequality relates to differences in access to social commodities including education and health care, but also social and institutional networks. While the EU has a clear role, and competences, in reducing inequality, still reducing inequality at national level within EU countries is a precondition for reducing European inequality.

### **3. Measurement of Inequalities**

The term disparity is a very frequent term in the last decades. It comes from the Latin word *disparitas*, which means divided. There exist a lot of definitions of the terms disparity and regional disparity in theoretical literature but also in encyclopaedias and explanatory dictionaries. In encyclopaedias we can mostly find nearly the same general characteristics of this term, while in technical literature disparity is usually of a territorial dimension or is objectively applied according to the needs of the given branch, i.e. in the case of this chapter – understanding disparities in the field of social quality, or better to say inequality. According to the dictionary, disparity is an inequality or difference. Usually it concerns inequality or difference as a result of a society development tendency and it is exactly the high level of their variability that results in development inequality. Thus, the social subjects and their parts, or the phenomena and processes running within them, are unequally developed and this results in their inequality or difference, i.e. among these subjects or their parts disparities are developing. To take disparities as a manifestation of complicated social subjects demands leaving single approaches and seeing the problems of disparities as a complicated problem demanding that the multidimensional approach is accepted in its research. Such an approach means, above all, a holistic (system) view on the research subject. That is why it is needed to expand the research to other dimensions as well (Melecký and Poledníková, 2012).

The recent interest in inequality is thus simply the recognition of the centrality of the topic to economic theory, policy, and performance. The recent return of the topic of inequality has been triggered by important contributions to the empirical analysis of inequality (Galbraith 2009), but these empirical analyses must be combined with an economic theory that is adequate to address the macroeconomic and microeconomic effects of inequality on social welfare. These problems are not always well diagnosed because the empirical measurement of inequality is often unable to take into account the geographical dimension of inequality, which is particularly complex in Europe. As Galbraith (2009) notes, if we take into account inequality in Europe as a whole, rather than focusing on inequalities within specific countries, we find that inequality in Europe is a much more serious problem than usually believed. To study inequality in Europe as a whole, one needs adequate statistical tools which can be used in the geographical and political context faced by Europe. Economic analysis is in need not only of an economic theory that focuses on the macroeconomic and microeconomic impact of

inequality, but also of economic measurement that takes into account the several dimensions of inequality across the EU, including the geographical dimension (Martins et al., 2015).

If such concerns are correct, it is essential not only to build institutional structures for the European social union but also to map social inequalities in the EU. The low growth performance in the EU over the recent decades has increased concerns regarding an increasing economic dispersion, income inequality at large, and social exclusion. Recent research works have stimulated fierce debate on inequality among academics and policy makers. The recent economic crisis has revealed many of the weaknesses of the current European economic policy, not least at the level of its fiscal policy, monetary policy, industrial policy and social policy, and its inability to address problems related to inequality. Inequalities in the EU have been the object of extensive research over the last decade. Regional inequalities or disparities – economic, social and territorial – among countries and especially regions is an important topic in the frame of the enlarged European Union. Not only the EU enlargement by the Central and Eastern European Countries, but also the economic crisis hit all the EU Member States hard, though the impact of the crisis varied considerably. The low growth performance in the EU has increased concerns regarding an increasing wage dispersion, income inequality at large, and social exclusion in line with poverty. Inequality should be seen as a cornerstone of both sustainable and inclusive growth. Social inequality in the EU is a very real problem which hampers sustainable economic growth. In the EU, the evaluation of the social development convergence and divergence trend among selected countries or regions is linked with the context of the cohesion concept, or social cohesion. The concept of cohesion can be distinguished in several dimensions – economic, social and territorial. It also corresponds to the dimensions of disparities. We can identify several approaches and methods of the measurement and evaluation of disparities among states and regions at the European level.

The level of social inequalities ranks among important indicators influencing the socio-economic development and other processes taking place in the social and economic realm. Facilitating rational income distribution and reducing poverty is mentioned as one of the main goals of the public policy. It should be mentioned that such multidimensional phenomena such as income disparity and poverty might be analysed from many different perspectives, including national and international, also within the EU. Striving for fairness in economic development is crucial in order for societies to be stable and citizens not to feel disenfranchised. The economic crisis has put inequalities high on the political agenda, and made this an issue of serious public concern. There is an increasing recognition that social policy can reduce inequality and poverty while simultaneously improving the economic functioning of the country with references to a high-employment economy delivering economic, social, and territorial cohesion in which the benefits of growth and jobs are shared, as mentioned e.g. Šotkovský (2016).

Multidimensionality and the holistic character of searching for regional differentiation problems concern namely the identification of their factors and determinants and diagnosing their content and scope, as also stated by Fojtíková et al. (2014, 2017). The above-mentioned system based on the form of multidimensionality or multidisciplinary results in the necessity to use plural research methodologies by using different research methods and techniques. There are two basic reasons why we want to identify the relevant characters of subjects as the bearers of given properties, to compare them and to examine them as the subject of our knowledge, our activity or our interest, as stated by Kutscherauer et al. (2010). The first reason is the need to identify and to examine the differences in the subjects' relevant characters; generally it is finding what the different subjects are, within a defined (given) set of states, countries, regions, municipalities, enterprises, etc., and what the impact is on their changes, namely the system changes in structure and behaviour. Generally this is such a dominant approach that finding the negative characters is often said to be a disparity approach. The

second, less frequent reason up to now is examining the difference of the subjects (their relevant characters), leading to understanding their uniqueness and capability to differ specifically and efficiently from the other subjects under examination and also e.g. to put their comparative advantages to efficient use. This means that capability plays a certain positive role. However, this must be measured in some way and some manner. The present regional practice assesses regional disparities or uses methods based on interregional comparison, under which selected regions are compared based on experience and knowledge, or based on statistical methods, the practical use of which, at the level of different institutions dealing with the problem of territorial differences, is nevertheless very limited. The identification and measurement of regional disparities is the basic condition for taking space-oriented economic-political measures with which it would be possible to minimise these disparities or to eliminate them (Wishlade and Yuill, 1997). Discussion relating to regional disparities is usually concentrated on the following questions (Wishlade and Yuill, 1997, p. 4):

- what type of disparity it concerns,
- what indicator can be used for identified disparity measuring,
- what factors determine this disparity,
- wider relationships of disparities in the national or international context?

Based on answering the above-mentioned question Wishlade and Yuill (1997) structured disparities into three dimensions including social ones, i.e. disparity decomposition in the social sphere. The quality of life in regions is affected by many factors conditioned on one another, as also Sucháček (2013) discussed. It is very complicated to separate economic and social factors not only in theory but also in practice. Each event usually includes both dimensions and it depends on the point of view which of them will be predominant for the given purpose. The social sphere co-generates conditions for guaranteed incomes that are reflected in the population's standard of living and affect the total social climate of the society.

There is ongoing and increasing interest in measuring and understanding the level, causes and development of inequality. European inequality, however, has been explicitly covered less often and only by Brandolini (2007) and Franzini (2009). Disparity measurement and evaluation at any level of territorial development is associated with a lack of integrated approaches and methodology in most cases. A relatively independent and in recent years frequently used approach to the measurement and evaluation of disparities in socioeconomic development is the construction of comprehensive integrated indicators and composite indices (CI) that represent a useful tool in policy analysis and public communication. Composite indicators or indices (CIs) which compare territorial (e.g. country, region, city or local municipality) performance are increasingly recognised as a useful tool in policy analysis and public communication and very common for benchmarking the mutual and relative progress of territories in a variety of policy domains. CIs as a tool for a ranking become more and more popular, because they illustrate a comprehensive view on a phenomenon that cannot be captured by only one single indicator. CIs provide simple comparisons of territories that can be used to illustrate complex and elusive issues in wide-ranging fields, e.g., environment, economy, society or technological development, etc. It often seems easier for the general public to interpret CIs than to identify common trends across many separate indicators, and they have also proven useful in benchmarking territorial performance. This reflects growing recognition of the important role that CIs can play as a tool for evaluating trends in level of economic, social and environmental development and for assessing the impact of policy on well-being. However, CIs can send misleading policy messages if they are poorly constructed or misinterpreted. In fact, CIs must be seen as a means of initiating discussion and stimulating public interest.

CI are very common in field of economics and are used in a variety of policy domains such as national or regional competitiveness, sustainable development, quality of life assessment, globalisation and innovation (see Huggins, 2003; Saisana and Tarantola, 2002). The proliferation of these indicators is a clear symptom of their political importance and operational relevance in decision-making processes (Table 2 supplies a sample of various types of composite indicators in the EU case). Also other non-EU institutions and authors have constructed CIs for measuring the level of development in demography, education, agriculture, infrastructure and social services and overall socio-economic development of different territories. A general objective of most of the CIs is the ranking of territories according to some aggregated dimensions. The OECD report clearly states that CI is formed when individual indicators are compiled into a single index, on the basis of an underlying model of the multi-dimensional concept that is being measured. CIs are valued for their ability to integrate large amounts of information into easily understood formats for a general audience. However, CIs can be misleading, particularly when they are used to rank country performance on complex economic phenomena and even more so when country rankings are compared over time. They have many methodological difficulties which must be confronted and can be easily manipulated to produce desired outcomes. Growth in the number of CIs in various policy domains raises questions regarding their accuracy and reliability. Given the seemingly ad hoc nature of their computation, the sensitivity of the results to different weighting and aggregation techniques, and continuing problems of missing data, CIs can result in distorted findings on territory performance and incorrect policy prescriptions. Despite their many deficiencies, CIs will continue to be developed due to their usefulness as a communication tool and, on occasion, for analytical purposes (OECD, 2008).

Importance and popularity of CIs nowadays is also evident in the EU that is confirmed by the establishment of the Composite Indicators Research Group (COIN) under the Joint Research Centre (JRC) of the European Commission (EC). The EU and its institutions intend to support and improve participation of local and regional authorities in the planning and implementation of the EU policies and activities on the ground also by contributing to improve sound statistics and data by exploring possible new ways of measuring and presenting regional performance. The EU stated that based on the available data from Eurostat, the EU therefore proposes to develop a territorial performance (in all the aspects) indicators/indices, which can provide additional insight into the future potential of territorial (especially local and regional) authorities in meeting the EU targets. Importance of CIs approach for the EU research is confirmed by the number of studies evaluating the level of development in specific thematic topic across the EU territory. Many approaches evaluating the EU in terms of CIs exist, but they are not included in evaluated sample with regard to extent of the paper and with regard to their progress in terms of theory and empiricism, timeliness and validity, e.g. An Indicator for Measuring Regional Progress towards the Europe 2020 Targets (European Commission, 2014), The Regional Lisbon Index (European Commission, 2010), Synthetic index: Regional perspective on the Lisbon Agenda (European Commission, 2007). The number of CIs in existence around the world is growing year by year (for a recent review see e.g. the author's own approaches to the CI issue (Melecký, 2016; Melecký and Staníčková, 2015) or Bandura (2006). CIs can be better to describe rather than to examine several independent indicators separately. On the other hand, they can send misleading messages to policy makers if they are poorly constructed or interpreted as evidenced by Nardo et al. (2005).

#### **4. Conclusion**

Inequality is a key problem facing the EU, and it has significant impacts not only on human well-being, but also on economic performance. This study has tried to show that inequalities in the EU are not a recent phenomenon and that they have in general increased over re-cent

times in most of the EU countries. As a general principle, it is important to note that many differences among people in the EU are created by society and systematically linked to life chances. The only way for the EU to meet these challenges is to not only strengthen economic growth policies through broad-based economic programme promoting marketization but also by resolutely pushing for the expansion of social aspects of the EU model (Allmendinger and Driesch, 2014). The future design of European economic policy must then provide a framework in which the policy instruments essential for a monetary, fiscal, industrial, sectorial, and social policy consistent with full employment and a reduction in inequality play a more prominent role. Europe 2020 is a credible strategy of industrial policy for the future of Europe and has the merits of presenting clear actions, clear targets and a detailed measurement strategy to monitor implementation. Combatting inequality should be considered as an instrumental target for both sustainable and inclusive growth. European policymakers have a long to-do list to foster inclusive growth in Europe (Darvas and Wolff, 2016). In all the countries of the EU, the welfare state has come under intense scrutiny as a result of budgetary pressures and wider societal developments. European social policy responses need national and regional contextualisation. Simultaneously, the EU needs a sense of common purpose and a common policy framework in support of national social policies. Its aim should be to create a virtuous circle whereby both pan-European cohesion and national cohesion are enhanced. Cohesion is about income and employment, but also about other dimensions of well-being.

Measurement of territorial progress with regards to achieving the developmental potential plays a crucial role in improving the prosperity and quality of life in any territories. This process has proved difficult as contemporary views on measurement of territorial development are multidimensional concepts. Several methods of evaluating the level of development exist, most of methods have their own limitations, especially in selection of relevant indicators and weighting scheme. Despite the limitations, several approaches in the form of composite indices has been proposed by the European Union (EU) and subsequent institutions for the EU evaluation in the field of cohesion, competitiveness, entrepreneurship, inclusive society, innovation, regional development and potential, resilience, social progress, etc. The necessity of having performance measured in terms of welfare beyond GDP calls for new approaches capable of simultaneously taking into account economic as well as social and environmental indicators. In recent period, efficiency has become very important part of governments' decisions, and the main reason are financial constraints that public finance need to face in setting of the financial crisis. So in given financial constraints, efficiency of public spending plays quite significant role. The convergence processes of the EU countries must be based on the strong socio-economic growth of GDP, investment flows, new technologies and productivity (Dvoroková, 2016). The recent trends of the EU economic development show a moderate GDP growth and require social legislation improvement, income level, labour market and education system development. Future social development investigations and governmental decisions need a pragmatic approach.

### **Abstract**

*Globalization generally refers to a process of broadening and deepening of interrelationships in international trade, foreign investment and portfolio flows. The outcome is the creation of a global marketplace for goods and services that is largely indifferent to national borders and governmental influence. Rapid technological change coupled with falls in barriers to international trade, have driven it. Also, World Trade Organization agreements and regional treaties forced domestic markets to open up. This development and the current wave of globalization of the economy has generated widespread interest among countries and within countries in the development and upgrading of national competitiveness. Globalization and national competitiveness are popular issues in economic policy debates of representatives of the world economic leaders, i.e. the post-war triad (in order of the EU, USA, and Japan) compared to rapidly developing BRICS (Brazil, Russia, India, China and South Africa) countries.*

### **1. Introduction**

In an increasingly global economy the future prosperity of a country depends more and more on the international competitiveness of its firms and industries. Policy-makers at all levels have been swept up in this competitiveness fever. This growing interest may perhaps be partly attributable to their awareness of the fact that all countries are having to contend with raised standards of economic efficiency as a result of the globalization of goods and factor markets. The economy may be competitive but if the economic, social and environmental society suffer too much the country will face major difficulties, and vice versa. Therefore governments in the long run cannot focus alone on the economic competitiveness of their country; instead they need an integrated approach to govern the country. Indeed, governments consistently may view these types' domestic policies as isolationist and limited approaches to economic efficiency (Halásková and Halásková, 2016). Some of the evidence of these changes includes some countries' implementation of economic policies that are designed to attract global investment, the prominent role of cross-border mergers and alliances, and the cooperation among national and sub-national governments. These features of the globalization process point to the need to examine the growing importance of a nation's competitiveness by investigating the

combination of specific competitive advantages as well as a nation's comparative advantages (it is reflected in its ability to create an environment conducive for trade and development).

In the European Union (EU), the process of achieving an increasing trend of performance and a higher level of competitiveness is significantly difficult by the heterogeneity of the EU Member States in many areas. Although the EU is one of the most developed parts of the world with high living standards, there exist significant differences having a negative impact on the balanced development across European countries, and thus weaken the EU's performance in a global context (Melecký, 2012; Muntean et al., 2010). Every European country has common features which affect and drive the competitiveness of all the entities located there, even if the variability of competitiveness level of the entities within the country may be very high.

The concept of competitiveness in the EU is but specific regarding the inclusion of elements of European integration that goes beyond the purely economic parameters. Studying the nature of the EU's competitiveness leads to the investigation of how the combination of comparative and specific advantages contributes to that competitiveness. In this paper we focus on competitiveness of the EU's international trade. The main aim of this paper is to examine competitiveness in the context of European nations by investigating foreign trade and its contribution to these nations' competitiveness. The focus of the research is to explain the impact of foreign trade on the productivity and identification of challenges or threats of competition of the world economic players.

## **2. Globalization and International Trade**

Economic theory suggests that globalization will lead to greater convergence in economic performance (including competitiveness performance) between open economies.

Foreign trade is one of the oldest and historically most important elements of economic relations. Currently, the foreign trade, resp. international trade is one of the most dynamic characters of globalized world economy due to the result of technological progress, the promotion of financial and trade liberalization that have led to the internationalization of production that has become an important tool for global development and growth. The term of globalization means an international interconnection of markets, which is caused due to the increasing mobility of factors of production and decreasing the distance between markets, that makes the national economy more dependent on each other. The impact of globalization is then higher, the greater the openness of national economies. Academics and practitioners have discussed this problematic in many theoretical and empirical studies.

Recent studies deal with the foreign trade based on most of the neoclassical theory approach of foreign trade. The comparative advantages of trade by David Ricardo, as well as the neoclassical Heckscher and Ohlin model dealing with the factor intensity of foreign trade and a new theory of foreign trade created by Paul Krugman, who work with different types of market structures in an environment of rising revenues of scale are used as a basic tools for research and recommendations to modern trade policy. The thoughts of classical political economy's representatives as Adam Smith, David Ricardo or John Stuart Mill, are based primarily on criticism of mercantilist doctrine. A faith of classical economists in the ability of the free market and specialization increase the wealth of the country became the basis for nowadays appearance of most foreign trade relations and it is the main reason for the liberalization of world trade. The original theory of comparative advantage shows the advantages of integration into the international trade on the basis of terms of profitability ratios. During the last century, the theory was subjected to many studies. For example (Drabicky and Takayama, 1979) point to the fact that in a globalized economy do not always apply the laws

of exchange ratios based on Ricardo's theory. Balassa (1965)] enriched the theories of revealed comparative advantage approach.

The neoclassical economists founded the theory of international trade on expanding the comparative advantages of additional factor of production - capital. The most important neoclassical theory is the Heckscher-Ohlin model, which works with both factors of production. Their theorem says that the country will specialize in the production of the goods, which is relatively intensive for the production factor (e.g. capital), which has an economy relatively more in comparison to the second factor of production (e.g. labour). However, the truth of this theory was denied by the American economist Wassily Leontief based on empirical research of the American economy. However, this work has had its critics as well. Many other authors have dealt with the validity of Heckscher-Ohlin model, e.g. Bagicha (1962), Jones (1956), Vanek (1963), Keesing (1966), Baldwin (1971), Leamer (1984) and Trefler (1995). Rybczynski (1955) referred to the situation that increase production of goods intensive in one kind of factor endowment under the influence of an unexpected growth of that factor, while the production of goods intensive in other factor of production decrease, whose abundance has remained the same. Stolper and Samuelson (1982) point to the fact that the economy's opening to foreign trade rises prices of goods of intensive factor, the price of goods also increases and vice versa. This theory was then examined by Metzler (1949), McKenzie (1955) or Chipman (1966). Among other criticisms of neoclassical theory is the fact that it doesn't work with the mobility of production endowments, transaction costs or mutual substitution of production factors. New trade theory is based on the standard model of international trade, which was created by Paul Krugman. This model responds primarily to the fact that each of neoclassical theory is narrowly focused on specific issues of foreign trade, but never affects the international trade as a whole. The second reason is a response to non-existent assumptions of perfect competition. A new theory of foreign trade is based on assumptions of economies of scale and monopolistic competition. This model was later extended to other economic aspects typical of the globalizing economy. Among the best-known studies can be included Ethier (1982), Brander and Spencer (1985), Eaton and Grossman (1986), Krugman (1994), Grossman and Horn (1987) or Grossman and Helpman (1992). The Melitz model (2003) working with heterogeneous firms is the last significant entry into the field of international trade theories.

It is evident that opinions and ideas regarding foreign trade and its benefits were continuously changed and evolved in time. Nowadays, among the most important channels of global integration are international trade and capital flows. Strong cross-border capital flows have been a major phenomenon in the new global economy as more and more countries embrace free markets and undertake trade and investment liberalization. Foreign direct investment (FDI) has strengthened the integration of individual national markets and has been a driving force in world trade and economic growth. Today the most modern and dynamic industries are transnational in scope since they are the result of an integrated system of global trade and production. Therefore, the development options for many countries depend, to a significant degree, on the kind of export roles they assume in the global economy and their ability to proceed to more sophisticated, high-value industrial niches.

Technological changes and the continuous fall in communication and transport costs have been a major factor behind global integration, and most countries are reversing import-substitution policies designed to prevent the need for trade. Governments are increasingly seeking to improve the international competitiveness of their economy rather than shield it behind protective walls. Most of countries have made tremendous progress in education and steady improvements in physical capital and infrastructure, thus boosting their productive capacity and enabling them to compete in world markets. This shift in development strategy has been

reinforced by communication technologies, which have made the world easier to navigate. Goods, capital, people and ideas travel faster and cheaper today than ever before.

International trade has come to occupy the centre stage in the economic activity, growth, and development processes of most modern societies. Today's world economic order (disorder) has simply rendered almost every modern economy to be heavily dependent on its foreign trade sector. And in no aspect is this trend more remarkable than the aspect of international competitiveness and the immense importance it now holds for the prospects of survival or failure of nations in their ability to obtain the maximum economic potentials from international trade. It can be stated that where international trade may be an engine that drives economic growth of nations, international competitiveness represents the fuel that empowers that engine (Ezeala-Harrison, 1999, p. 3).

### **3. International Trade and Competitiveness**

In recent years, the topics about measuring and evaluating of competitiveness have enjoyed economic interest. Although there is no uniform definition and understanding of competitiveness, this concept remains one of the basic standards of performance evaluation and it is also seen as a reflection of success of area (company, country, region) in a wider (international, interregional) comparison. Competitiveness is monitored characteristic of national economies which is increasingly appearing in evaluating their performance and prosperity, welfare and living standards. The exact definition of competitiveness is difficult because of the lack of mainstream view for understanding this term. Competitiveness remains a concept that can be understood in different ways and levels despite widespread acceptance of its importance. The concept of competitiveness is distinguished at different levels – microeconomic, macroeconomic and regional. Anyway, there are some differences between these three approaches; see e.g. (Hančlová and Melecký, 2016; Hančlová and Staníčková, 2013; Melecký and Skokan, 2011; Krugman, 1994).

The need for a theoretical definition of competitiveness at macroeconomic level emerged with the development of globalization process in the world economy as a result of increased competition between countries. In order to understand what the competitiveness is in a national perspective, it is best way to look at definition given by the President's Commission on Industrial Competitiveness (President's Commission on Industrial Competitiveness, 1985): "Competitiveness is the degree to which a nation can, under free and fair market conditions, produce goods and services that meet the test of international markets while simultaneously maintaining or expanding the real incomes of its citizens." This is the most quoted definition in this area, and defines competitiveness from a macro perspective. Many writers (Barrell et al., 2000; Krugman, 1994; Starr and Ullmann, 1988; Tyson, 1988] have also referred to this definition of competitiveness of nations. The definition points out that the ultimate goal of competitiveness is to maintain and increase the real income of its citizens, usually reflected in the standard of living of the country. From this perspective, the competitiveness of a nation is not an end but a means to an end; its ultimate goal is to increase the standard of living of a nation under free and fair market conditions (through foreign trade, production, and investment). It "refers to a country's ability to create, produce, distribute, and/or service products in international trade while earning rising returns on its resources" (Srcoot and Ullmann, 1988, p. 3]. Arguably, national governments' principal goal is to establish an environment that fosters a high standard of living for its citizens by addressing health, safety, laws, and environmental issues. This goal can be achieved, in part, through effective management and allocation of resources for producing the highest attainable level of products. Therefore, it becomes imperative that governments coordinate a comprehensive approach towards trade and investment that incorporates a competition orientation (Feketekuty, 1996).

Indeed, many nations are very cognizant of the fact that internal growth depends upon their ability to sustain trade and attract foreign investment.

The concept of international competitiveness of nations makes sense only within a national economic context. Nations adopt economic and trade policies that directly affect the ability of enterprises and industries engage in international trade and investment. This concept is thus often used in analysing countries' macroeconomic performance. It compares, for a country and its trading partners, a number of salient economic features that can help explain international trade trends. There have been several studies devoted to the competitiveness of international trade. Authors focus either on one particular country and its foreign relations, or discuss the situation of a certain union of countries with respect to its environment or the situation within it. In his book, *The Competitive Advantage of Nations*, Porter (Porter, 1990) observes that national competitiveness is measured by two sets of indicators: "(1) the presence of substantial and sustained exports to a wide array of other nations, and/or (2) significant outbound foreign investment based on skills and assets created in the home country" (p. 19). He notes that the competitive advantage of nations is determined by the strength of their factor endowments; their demand conditions; the competitiveness of firm strategies, structures, and rivalries in major industries; and the strength and diversity of related and supporting industries. It should be emphasized here that openness to global markets and the internationalization of economies play an increasing role in productivity and competitiveness enhancement.

#### **4. Conclusion**

There is little doubt that international trade is vital to a nation's wealth. Trade increases access to global resources and extends market reach. Certainly, one of international trade's fundamental principles is that cross-border trade enables global trade efficiency. The argument that is generally presented is that individual countries are able to maximize their potential for growth because they are able to trade particular export commodities in which they have a comparative advantage. At the same time, the country will import those commodities in which they do not have comparative advantages. This situation creates an ideal balance of freer world trade that ultimately contributes to global efficiencies through specialization. Under these considerations, it becomes apparent that countries may not have a choice but to adopt and implement policies that are designed to employ national resources efficiently. Otherwise, countries may end up squandering their resources on unproductive commodities.

The dynamics of economic, social, political and cultural change in the contemporary world are increasingly shaped by the pursuit and promotion of competitiveness. Competitiveness of economies in integrated world determines how well they convert the potential created by access to global markets into opportunities for their economic subjects. The world economy is changing in the face of growing competition as consequence of globalisation processes. These processes result in changing position of global economic powers, emergence of new powers, and thus in new distribution of global forces. It leads to importance of deeper study of factors affecting competitiveness and influencing the growth with respect to competitors and market players. As part of the follow-up research, due to the interconnectedness of world economies as a result of globalisation processes, it is desirable to analyse macroeconomic competitiveness not only for economic objectives but the other ones. Competitiveness is multifactor conditional, it is necessary to include social, environmental, institutional, etc. aspects. In reality, improving competitiveness simply means to create conditions that allow economy to allocate scarce resources where opportunities arise as external and internal conditions change. Understanding of how policies interact to affect competitiveness, at macroeconomic level is important. Competitiveness is often presented as a relative concept, which leads many to see competitiveness policy as a zero-sum game. Competitiveness of economies in integrated world

determines how well they convert the potential created by access to global markets into opportunities for their economic subjects. In reality, improving competitiveness simply means to create conditions that allow economy to allocate scarce resources where opportunities arise as external and internal conditions change. At global level, uncooperative national policies are a primary constraint to competitiveness. And as production increasingly transcends borders, the spill over effects of domestic policies multiply in number and size. Improving competitiveness is as much a collective effort as an individual one. Countries that want to boost productivity of own economies need to cooperate to have functioning and up-to-date supranational institutions and frameworks (WEF, 2015; Fojtíková, 2013). The world economy is changing in the face of growing competition as consequence of globalisation processes. These processes result in changing position of global economic powers, emergence of new powers, and thus in new distribution of global forces. This leads to importance of deeper study of factors affecting competitiveness of economies and can influence its growth, also with respect to existing competitors and strong players.

In this connection, the EU Communication called Global Europe: Competing in the World (EC, 2006, p. 20) is the initial idea for the further research: "China is the biggest single challenge of globalisation in the trade field and a test for our capacity to make globalisation an opportunity for jobs and growth." It is obvious the continuity of the EU's growth strategies (the earlier Lisbon Strategy, the current Europe 2020 Strategy). As part of the follow-up research, the aim will be to assess development of the EU and China, resp. of all global economic powers. Due to the interconnectedness of world economies as a result of globalisation processes, it is desirable to analyse competitiveness of these entities not only for economic objectives but the other aspects. Competitiveness is multifactor conditional, it is necessary to include social, environmental, institutional, etc. aspects. Also, stage of economic development plays key role in strengthening of competitiveness. World Economic Forum applied this concept of Michael Porter (1990) for competitiveness evaluation of countries in Global Competitiveness Report too. Each stage of development (economy is driven by productive factors, investment-driven economy, and innovation-driven economy) corresponds to another type of competitive advantage, i.e. generally cost-effective or qualitative one. Competitive advantage is related to ability of economy to compete, and also with needs of economy for concrete measures to improve its position – this differs naturally across stages of economic development. For example, China mentioned in the EU Communication (EC, 2006) as country that is currently the biggest opportunity, challenge and also threat. China faces great challenges in terms of addressing socially and environmentally friendly issues in terms of competitiveness and international trade relations. This fact is in line with its stage of economic development and corresponding competitive advantages (Vahalík and Fojtíková, 2016). Follow-up research will orientate on input factors, i.e. driven forces of competitiveness of countries in international comparison and analysis of their competitive advantage and disadvantages. Understanding of how policies and institutions interact to affect competitiveness, at level of economy is important.

### **Abstract**

*The article highlights the issue of reconstruction of EU-funded historical monuments (through calls) and the role of subsidy titles in the context of cultural heritage protection. The examples from the Czech Republic and the Moravian-Silesian Region outline some pitfalls in the reconstruction of heritage buildings, consisting in particular in specific requirements, imposing high financial demands on investors and the expertise of implementing companies. The author draws attention to the long-term and strong underfinancing of the area of cultural heritage care in the Czech Republic and the significantly different overall character of the Czech Republic's heritage fund compared to the traditional EU countries. The text highlights the great importance of pre-project preparation of the construction and its impact on the overall budget. An example of implementation that has received the highest European award in the field of monument care highlights the great importance of European subsidies in the field of cultural heritage care.*

**Keywords:** *calls, Czech Republic, Europa Nostra, European Union, IROP, monuments, Subsidies*

**JEL Classification:** *H20, F63, Z19, Z32*

## **1. Introduction**

The area of monument care is a field with more than a hundred years of tradition and a huge, though not at first sight obvious, economic and cultural benefit. European integration has not escaped this field in the good sense either.

It manifests itself in several different ways. Perhaps the most tangible is the direct cooperation in the area of reconstruction of monuments, funded by a wide range of subsidies. In terms of volume of funding, a number of subsidies, the common denominator of which is the European Union, are very important. These subsidies with different names have a common denominator, which is a large sum for the reconstruction of buildings. This distinguishes them from a number of subsidies provided by the Czech state. The disadvantage is the complicated administration when drawing subsidies with a number of conditions. EU funding is allocated through calls from the so-called IROP (Integrated Regional Operational Programme).

### **1.1 EU Funding**

EU funding is allocated through calls from the so-called IROP (Integrated Regional Operational Programme).

### *1.1.1 IROP Calls*

In total, IROP managed to announce 76 calls worth 111.5 billion CZK (Quarterly of Integrated Regional Operational Programme, [online] 02/2017). At the end of August 2017, 2 596 applications worth over 44 billion CZK were positively evaluated. In the area of culture which accounts approximately for 8,5% of the total funds, grants for monuments are awarded from calls No. 13 proclaimed for the revitalization of selected monuments, announced in November 2015, from call No. 21 „Museums“, and call No. 52 „Revitalization of Selected Monuments“ II and call No. 76 „Museums II“, announced in August 2017.

### *1.1.2 Call no. 13*

Under call No. 13, 54 projects were approved for more than 3 billion CZK. These included, for example, the revitalization of Kost Castle, the reconstruction of the national cultural monument of Karnola in Krnov, the reconstruction of the Cathedral of St. Bartholomew in Pilsen, digitizing Sv. Kopeček Church in Olomouc and others. For the great interest in call No. 13, call No. 52 was again proclaimed, with a budget of 1.55 billion CZK. This call was exceeded by the applicants approximately 3 times. The projects submitted in this call are now in the approval process and, at the same time, during the month of August, the volume of funds was increased to 3.1 billion CZK.

### *1.1.3 Call no.21*

Under call No. 21 „Museums“, designed to protect and use collection and library funds, preservation and restoration of collection items, digitization of collections, construction of new depositories and new expositions. From this call 39 projects with a value of 2.1 billion CZK were approved. The supported museums include, for example, the TATRA Car Museum in Kopřivnice, the Museum of Těšín or the Comenius Museum in Přerov, the opening of new exhibition rooms at the Roštejn Castle, the reconstruction of the castle in Studénka Nová Horka and others.

### *1.1.3 Call no.76*

On 17 August 2017, a new call No. 76 „Museums II“ was announced in the total value of 900 million CZK. Support for cultural heritage also continues under calls No. 41, 48 and 55 of the IROP for integrated instruments. Monumentally protected buildings and museums are becoming more and more the target of trips and hide tremendous potential, so they are present an investment for the future (Quarterly of Integrated Regional Operational Programme, [online] 02/2017).

**Table 1: IROP Calls in the Field of Monument Care**

Call no.	Name of the Call	Allocated EU funds (in million CZK)
76	Museums II.	900
55	Cultural Heritage – Integrated CLLD Projects	427.5
52	Revitalization of Selected Monuments II.	1,500
48	Strengthening the Presentation, Enhancing the Protection and Development of Cultural Heritage – int. Proj. ITI	1,140
41	Strengthening the Presentation, Enhancing the Protection and Development of Cultural Heritage – int. Proj. IPRÚ	503.8
21	Museums	2,115
13	Revitalization of Selected Monuments	3
Total		9,580

## 2. Problem Formulation and Methodology

Reconstruction of protected buildings is one of the most difficult tasks in the building industry. A number of specific activities, without which reconstruction would have been impossible, follows up with ordinary construction work. It is necessary to coordinate common construction works with specialized craft work and restoration work, archaeological surveys and a number of specific requirements from the area of heritage care, firemen, hygiene, etc. All these, often contradictory, requirements need to be aligned. Therefore, the design phase is key to the reconstruction process (Henderson, Nakamoto 2016). Specialized craftwork and restoration work, which runs in other way than usual renovation work, necessarily increases the budget of the construction and from the very beginning of the design preparation it is necessary to count with this fact. Well-managed project and a properly designed budget is necessary not only for the approval of the project and the grant of the subsidy, but also for the successful implementation of the restoration of the monument. A large group of people of different professions is involved in the process of reconstruction from the very beginning.

Despite the great efforts of a number of professionals in various professions, the successful reconstruction of monuments sometimes hits the often unjustified criticism from the public (Lithgow 2013). It is argued that the invested means are "not visible", which is often the case with specialized restoration works. The public also criticizes the size of renewal of individual building parts, which is either too big or too small in their eyes. Even with the reconstruction of Kuks, awarded the Grand Prix Europa Nostra, these comments were raised by the public. A large percentage of highly specialized work generates a number of uncertainties that manifest only during the implementation and which often have a relatively large impact on the budget of the construction. This is closely related to the fact that investors, but sometimes also grant providers, are particularly underestimated in the survey phase, which includes a number of specialized activities from various fields.

Even if the survey phase is well-done, often the actual realization of the building is not surprising in the form of increased costs - due to a worse condition than expected (National Heritage Institute [online] 2017). Typical examples are restoration work on altar architectures, which at first glance look cohesive, but after the dismantling of the piece, a large extent of destruction of wood appears under a series of glue-chalk polychromic layers. Restoration of

the destruction of such wood piece is financially expensive and petrification is sometimes not even possible. This is why the copies have been used to replace the original work which is also very expensive. In the case of these works, it involves amounts in the order of hundreds of thousands CZK. The restoration of altars is usually in the order of millions of CZK, and, in case of an unexpected bad condition, the budget for the repair can be greatly increased.

Also, the revelation of the original wall paintings can provide a number of surprises, which can have an immediate effect on the budget of the work. Wall painting hidden under the newer layers of plasters and paints may be more damaged than expected from the probes made, or may be completely absent. After the discovery, the investor faces the problem of what to do with such a preserved and exposed painting. To preserve, reconstruct, or combine both? The final verdict is not only a question of the concept of restoration intervention related to monument care, but also a financial issue that has a considerable impact on the budget of the work (Girsa V. et al. 2004). Therefore, it is necessary to count on the exploratory phase of the design (even destructive) that at least partially eliminates these unexpected costs of the work.

A high level of monument care in the Czech Republic was confirmed by the Europa Nostra 2017 European Heritage Prize („Oscar“ prize for monuments), which our country won this year with a project of reconstruction of the baroque premises of the Kuks Hospital funded by the Integrated Operational Programme, the predecessor of IROP. Extensive and costly reconstruction of Kuks could not have taken place without EU funds. „Renovation of the Kuks Hospital as an integral part of the building and landscape protection project is of the highest quality. Its multidisciplinary and interdisciplinary approach is considered commendable and should serve as a convincing example for other renewal projects in Europe“ (Europa Nostra [online] 2017), states the preamble to the Grand Prix Europa Nostra.

## 2.1 Model and Data

Reconstruction of Kuks has been exceptional within the EU and the Kuks complex itself is exceptional. Franz Anton Sporck built a unique complex in Europe that included a spa with a castle on one side and on the other side a baroque landscape with a hospital, garden, monastery and cemetery. To this day, however, the area has been preserved in a torsional state, the castle building disappeared in the past.

### **3. Problem Solution**

In 2009, a working group was set up to prepare a grant application. In the course of 2009, documentation was prepared as part of the pre-project preparation. The historical building survey, the geodetic survey of the complex, the evaluation of the construction technical condition of the buildings within the hospital and the reconstruction of the hospital garden and the green area were carried out. A key document was the study of the feasibility and economic evaluation of the project, essential for the project application as well as for its own project. The general reconstruction of the extensive baroque Kuks complex took place in the period 2013-2015 and the final price was 453 million CZK (National Heritage Institute [online] 2017).

The project documentation for the reconstruction and future use of the site was elaborated. In May 2010 the application was positively evaluated and it was decided to allocate a European subsidy for the reconstruction of the hospital area (Revitalizace Kuks [online] 2017). In 2011, the construction site and rescue archaeological survey of the site was launched in the amount of 6,102,000 CZK while the necessary territorial and building permits were issued. In April 2013, a tender for the construction contractor took place, won by the Hochtief - Gema Art association. In the course of 2014, the entire complex of Kuks hospital was closed and construction works, archaeological research and restoration work started. Not only buildings, but also gardens were restored.

The reconstructed premises have gained new cultural use. There is a ceramic workshop, accommodation spaces, expositions, a theatre, and a variety of events focused on various interest groups. The main bearer of the project was the site administrator, the National Heritage Institute, regional office in Josefov, the partners of the project were also the Faculty of Pharmacy of Charles University, the Museum of East Bohemia in Hradec Králové, the Hradec Králové Region, the town of Kuks and others. Pharmacy students in the hospital will be attending part of the lessons related to the historical development of their disciplines (Drha 2005). The products of the restored herb and fruit gardens will be used in follow-up educational programmes, which also involve active engagement of the public. Relatives of patients with multiple sclerosis will attend seminars focused on the ability to cope with severe family illness. There will be thematic history and art lectures, seminars and workshops for the professional and non-professional public or teaching programmes for schools. The depositories and library of the Kuks monastery will be made available to researchers (Revitalizace Kuks [online] 2017). The successful reconstruction has also been positively reflected in the attendance and economic benefits of the hospital (see Table 2 and Figure 3 below).

**Table 2: Total Arrivals of Visitors at Kuks Hospital from 2003 to 2017**

Year	Visitors

**Figure 3: Development of Visitor Arrivals at Kuks Hospital 2003-2017**

Source: own elaboration (2017)

The reason for the increase of visitors in 2007 was the extension of the existing hospital exposition and the opening of the Count Sporck tomb. Six new rooms were also opened within the existing guided tour. The gradual drop in visitor arrivals since 2010 is related to the dampening of activities and investments in connection with the expected start of the Kuks -

Pomegranate project. In 2014, the monument was closed for the visitors due to reconstruction. The increase in attendance in 2015 relates to the completed reconstruction of the Kuks - Pomegranate project.

#### 4. Conclusion

However, much more examples of reconstruction of monuments with EU money can be given. That is not the purpose of this paper. The aim is to show the positive role that the EU has in the field of cultural heritage conservation (Kouřilová, Pělucha 2017). The nature of the defects of the historical buildings is different in the former Eastern Bloc countries than in the West. In the former Eastern Bloc countries, which also applies to the Czech Republic, the continuity of ownership and hence the care for cultural wealth were broken.

After the accession of the Czech Republic to the EU, a number of unused sites of immense historical and economic value remained in the territory of the country and could not be repaired without a considerable amount of funds.

The area of cultural heritage care has been significantly underestimated in the Czech Republic for more than 60 years (and the post-revolutionary period has not changed that) and without the EU's help, the reconstruction of a number of buildings could not be conceived at all.

Another specific feature of the monument fund is a large number of castle and chateau complexes with wealthy state-owned mobiliary funds. While these buildings generate significant income from entry, events and leases, maintenance costs are often higher than profits.

However, these buildings are the "family silver" of the Czech state, it is necessary to take care of them adequately and to see them as a property that does not lose its value over time, but increases. Here too, the area of EU subsidies is particularly important. The repaired cultural monuments are a magnet for visitors who, in addition to their own visits to the monuments, need services in the form of accommodation capacities, restaurants, shops. This has a positive impact on employment in the area and the development of the region. Nowadays, when Europe is thriving in the belief of the migration crisis, cultural heritage in the form of cultural monuments is more than ever an important symbol of our European Christian identity and an indicator of the nation's culture, capable and willing to take care of the ancestral heritage. Investing in the restoration of cultural heritage is an investment in the future.

### **Abstract**

*Business services play an increasingly important role in the European economy. At the same time, they are suffering from different barriers regarding their provision within the EU internal market. Therefore the European Commission has taken steps to improve functioning of the internal market for business services. The aim of the paper is to discuss the present situation in European business services sector in the light of fulfilling the internal market idea. The conclusion is that due to the regulatory heterogeneity and administrative obstacles the aim of the internal market idea has not been achieved. Furthermore, the negative appraisal of the last proposal of the European Commission by some Member States and the European advisory institutions is not a good prognostic to the possibility of fulfilling and strengthening the internal market in the business services sector in the EU.*

**Keywords:** barriers, business services, internal market, regulatory heterogeneity

**JEL Classification:** F15, F55, O52

### **1. Introduction**

Business services play an increasingly important role in the European economy as high-quality business services are crucial to its competitiveness, as well as in recent decades have been an area where most jobs have been created. At the same time, the business services sector is suffering from different barriers regarding their provision within the EU internal market. Some barriers are natural (e.g. language, features of the type of service), other are of regulatory and administrative nature. In 2012 only 3% of architects worked in another EU Member State, and less than 2% of accountants applied to establish an office or to work temporarily across the EU borders in 2014 (Doemeland et al, 2016). In 2015 the European Commission has taken first actions to improve functioning of the internal market for business services, what resulted in the proposal of service package in 2017. The aim of the paper is to discuss the present situation in European business services sector in the light of fulfilling the internal market idea. To achieve the aim the following issues will be analysed: the importance of business services for the European economy, types of barriers hampering the free provision of business services in the EU internal market, regulatory heterogeneity and actions that have been undertaken by the European Commission towards the realization of the internal market concept regarding business services. The paper is based on the analysis of the European documents and literature on the topic, as well as using data from the Eurostat database. The regulatory heterogeneity and restrictions in business services sectors are analysed based on raw data contained in the OECD database on Service Trade Restrictiveness Index.

## 2. Setting the Scene

Business services involve one company providing services to other companies in support of their activities. The concept of business services covers a broad spectrum of services ranging from professional (e.g. software and computer services, strategy and management consultancy, legal and tax advice, auditing, advertising, headhunting) through technical services (e.g. design, engineering, or architectural services) to operational support (e.g. administration, bookkeeping, security services, facility management, labour recruitment, industrial cleaning) (Kox and Rubalcaba, 2007; Thelle and Nielsen, 2013). Professional services and technical services are often combined and labelled “knowledge based services” or “knowledge intensive business services”. The business services sector refers to the economic activities covered by NACE Rev. 2 Divisions 62, 69, 71, 73 and 78 and Groups 58.2, 63.1 and 70.2, and the enterprises or parts of enterprises that carry out those activities (Eurostat [online], 2018a).

The business services sector has experienced a remarkably strong growth process in the past two decades, in term of both value added and employment. In 2003 business services generated 1,067 billion euro accounting for 11% of the total EU15 economy with around 19 million workers (Kox, Rubalcaba 2007), whether in 2009 it reached 1,518 million euro (11,7% of the EU27 economy) with 20.5 million of people employed (European Commission 2012). But the most spectacular growth in development of business services sector has appeared in last few years and in 2016 it accounted for nearly 12% of the EU28 value added with over 29 million people employed (Eurostat [online], 2018b).

The same phenomena is noticeable in all EU Member States, however the situation is quite different between them. Based on the data provided by Eurostat ([online], 2018b), we have noticed that the biggest business services sector in value terms is in Germany with €312,6 billion of turnover in 2016, followed by United Kingdom (€264,2 billion) and France (€262,5 bln). However taking into consideration the share of business services sector in country’s value added and employment, the leaders are the Netherlands (15,1% and 20,8% respectively) and Belgium (14,2% and 19,5%). They are followed by France, Malta, United Kingdom and Luxembourg with over 12% share in country’s value added and over 14% share in employment. The least business services oriented economies are Greece (5,1% for value added share), Bulgaria, Czech Republic and Lithuania (below 7% of value added).

The development of companies together with changes in technologies and outsourcing processes are incentives for increase in international trade in services. Business services are amongst the ones to be traded the most. In 2016, export of business services accounted for 26% of total UE export, while import for 30%. In both cases intra-EU trade prevailed over extra-EU, however as for export difference was very small (51% for intra-EU versus 49% for extra-EU trade) whether for import slightly bigger (54% intra-EU versus 46% for extra-EU) (WTO [online], 2018).

## 3. Regulations and Barriers in Provision of Business Services in the EU

The business services sector in the EU is regulated on two levels: community and national. The basic principles are set up by the EU treaty provisions concerning the internal market that constitute the basis for more detailed regulations. In the case of business services it is the Services Directive (123/2006). The Services Directive offers a harmonised framework for making better use of the classical single market freedoms of physically providing services cross-border or setting up an establishment in another Member State (European Commission 2017a). Therefore the aim of the Directive was twofold: firstly, to eliminate obstacles to the development of service activities between Member States and, secondly, the establishment of

general provisions facilitating the exercise of the freedom of establishment for service providers and the free movement of services, while maintaining a high level of quality of services. It should be emphasized that the Services Directive applies only to requirements which have a direct impact on the taking up and pursuit of service activities, and does not apply to requirements which should be followed in conducting such activities (Stefaniak 2016).

Free movement and free establishment in services, so then in business services, across intra-EU borders is guaranteed by the supranational regulations, however there are still barriers hampering the realisation of the European internal market. That happens because, firstly, the Member States used different implementation strategies (Stelkens, Weiss and Mirschberger 2012) and, secondly, the Services Directive does not intend to harmonise national regulations leaving room to different attitudes and solutions to be applied. As Mustilli and Pelkmans (2013) noticed, the Services Directive has undoubtedly reduced regulatory heterogeneity in the domains with relatively light regulatory requirements, but in more heavily regulated service sectors this heterogeneity is still rather high, becoming an obstacle to market access.

The obstacles in the business services sector can be recognised as regulatory or administrative barriers that might affect the free provision of business services in the form of cross-border transaction or establishment or both. The European Commission (2015a, 2015b, 2017b) has recognised the following barriers regarding business services:

a. Regulatory barriers:

- various authorisation regimes in scope and types of business services.
- requirements on the legal form of service providers, their shareholding structure, the allocation of voting rights and management positions.
- requirements on compulsory chamber membership.
- a considerable number of insurance requirements.
- strict requirements in several Member States in relation to multidisciplinary activities.
- multiple authorisations, registration or prior notification requirements.
- impose of tariffs by some Member States concerning different business services.
- restrictions on advertising and marketing activities.

b. Administrative barriers:

- a substantial number of documents required in certified or authenticated form and lack of acceptance of documents of equivalent purpose for the authorisation schemes or notification procedures.
- multiple authorisations, registration or prior notification requirements that are also complicated, lengthy (up to six months) and costly to comply with.
- handling fees - authorities may charge fees for the initial authorization and for (often compulsory) membership.
- differentiation of time validity of authorizations and therefore need to renew authorization at different time and cost.
- weak performance of the Points of a Single Contact – lack of business information in other languages than a native one, different structure of the information content, little or no online information on requirements available (registration forms for authorization procedures can usually be downloaded from the websites of the chambers).
- lack of electronic registration and authorisation possibility in most of Member States – need to send documents by regular mail or sometimes even to deliver in person.

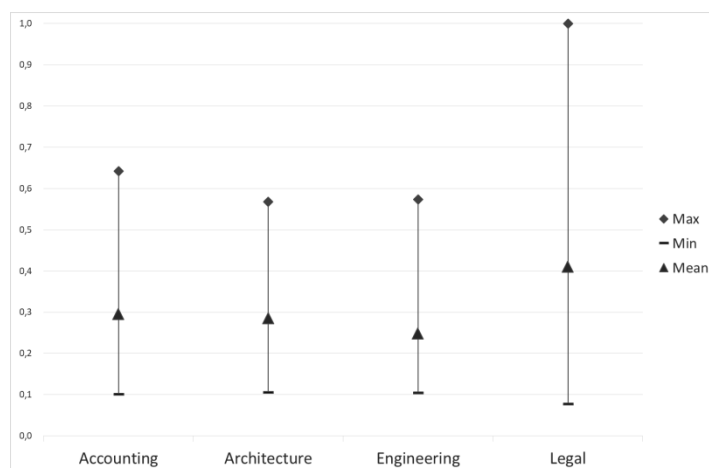

#### 4. Regulatory Heterogeneity in the EU Business Services Sector

The regulatory heterogeneity is one of the main barriers in the international trade in services. The different research (Marel and Shepherd 2013; Nordas 2016; Nordas and Rouzet 2017) show that regulatory heterogeneity have a significant negative effect on services trade flows. In general, heterogeneity of regulations is reflected in restrictions on foreign entities (establishment), movement of people (providers of services), barriers to competition, regulatory transparency and other discriminatory measures. All of them together are reflected in the Service Trade Restrictiveness Index (STRI) (OECD 2018 [online]). The STRI measures the restrictiveness of the national regulations based on the similarity of answers to the same measures between the country pairs. It is a composite index taking values between zero and one, where zero is representing an open market and one a market completely closed to foreign services providers. The STRI is a measure of Most-Favoured Nation (MFN) basis and does not take into account any specific concessions (Geloso Grosso et al., 2015).

The four types of business services are being in the scope of particular interest of the European Commission when it comes to strengthening of the European internal market. These are: accounting services, architecture, engineering and legal services. The general overview of regulatory heterogeneity in those four types of business services is presented below.

The STRI index shows that there are differences between those four business services regulatory frameworks between the EU Member States (Figure 1). Architecture and engineering services are quite similar in terms of the average restrictiveness (0,29 and 0,25 respectively) and dispersion (0,46 and 0,47). The accounting services are characterised by greater differences between the EU Member States, even though the average restrictiveness is on the similar level as in architecture and engineering. The greatest dispersion of restrictiveness appears in the legal services. The highest score there is one, what means that these countries are closed to foreign service providers (Luxembourg and Poland). On the other end is one country with nearly no restrictions (Latvia with the STRI index of 0,08). The average restrictiveness for legal services accounts for 0,41.

**Figure 1: STRI Indices - Accounting, Architecture, Engineering and Legal Services**

Source: own elaboration (2018) based on OECD STRI database [online] (2018)

Accounting, architecture, engineering and legal services not only vary in terms of the average restrictiveness, but also as far as the dispersion of restrictiveness is concerned. However in all cases the restrictions derive from restrictions on movement of people and restrictions on foreign entry (Table 1). The highest average restrictiveness for movement of people characterise legal and architecture, whether for foreign entry in legal and accounting. The lowest level of restriction appears in barriers to competition.

**Table 1: Regulatory Heterogeneity in Business Services – Summary Statistics**

Measure	Accounting				Architecture			
	Mean	Std. Dev.	Min	Max	Mean	Std. Dev.	Min	Max
Restrictions on foreign entry	0.127	0.064	0.046	0.379	0.057	0.031	0.023	0.173
Restrictions on movement of people	0.123	0.045	0.031	0.215	0.163	0.097	0.048	0.318
Other discriminatory restrictions	0.010	0.007	0.000	0.022	0.014	0.010	0.000	0.045
Barriers to competition	0.008	0.004	0.000	0.016	0.011	0.006	0.000	0.020
Regulatory transparency	0.027	0.014	0.009	0.055	0.041	0.020	0.014	0.008
	Engineering				Legal			
	Mean	Std. Dev.	Min	Max	Mean	Std. Dev.	Min	Max
Restrictions on foreign entry	0.052	0.032	0.024	0.177	0.185	0.137	0.021	0.478
Restrictions on movement of people	0.134	0.091	0.032	0.322	0.164	0.084	0.028	0.347
Other discriminatory restrictions	0.031	0.009	0.000	0.028	0.014	0.012	0.000	0.045
Barriers to competition	0.009	0.004	0.000	0.019	0.018	0.013	0.000	0.047
Regulatory transparency	0.041	0.021	0.014	0.083	0.030	0.021	0.008	0.082

Source: own calculations (2018) based on OECD STRI database [online] (2018)

The STRI indices vary also between countries (Figure 2). The highest scores of 1 appears for Luxembourg and Poland in legal services, followed by France and Lithuania. Poland also has quite high level of restiveness in other business services in consideration, whether in Luxembourg these restiveness levels are on lower levels. Portugal is the country with the overall high restiveness level in all business services sectors concerned as STRI takes values over 0,4 for all of them, whether in France, Slovakia and Poland three business sectors have STRI scores much over 0,4. The less regulatory restrictive country is Latvia – neither of indices accounts for more than 0,1.

**Figure 2: STRI Indices in the EU Member States Concerning Business Services**

Source: own calculations (2018) based on OECD STRI database [online] (2018)

## 5. The EU Initiatives Regarding Business Services

As there is no room for the harmonization of regulatory framework, the European bodies has concentrated on the actions aiming at reduction of administrative barriers. In answer to the lack of the Service Directive results in significant changes in the regulatory, but mainly in the administrative environment for services, the European Commission has presented in 2015 a new strategy for internal market: *Upgrading the Single Market: more opportunities for people and business* (European Commission, 2015c). This strategy made a basis for a services package: *A services economy that works for Europeans* that consist of four proposals (European Commission [online], 2017c).

The strategic importance for the business services provision across the EU internal market has a proposal of the European Services e-card. In general, it is a simplified electronic procedure that will make it easier for providers of business services to complete the administrative formalities required to provide services abroad in another EU country. It shall replace administrative formalities in different languages, since the service provider follows a procedure in the home country language and with the home country administration. As results: the elimination of some administrative barriers and greater transparency of national requirements are expected. On the other hand the e-card is not aiming in harmonization, in general, of administration procedures across the EU, additionally leaving the possibility to the Member States to reject suggested application of procedures.

At the moment of proceeding the paper, the possibility of realization of the European Commission's proposed service package is weak, as there is a significant opposition from some protectionist EU Member States (France, Germany, Austria, Luxembourg, Belgium), as well as negative appraisal from the European Parliament commissions (ECON, JURI, EMPL) and the European advisory institutions (The European Economic and Social Committee, the European Committee of the Regions) (European Parliament [online], 2018). If the internal market and Consumer Protection (IMCO) committee of the European Parliament will also give a negative opinion it is a high probability that this proposal will not be further proceeded.

## 6. Conclusion

The business services market in the EU is highly fragmented and providers of these services face many barriers when they decide to carry on their activities in other Member States than the home country. These barriers are very diverse in nature ranging from natural through regulatory to administrative obstacles. Furthermore, even though the free provision of services across intra-EU borders should be guaranteed with the EU supranational enforcement regime, the EU's Member States still retain considerable discretion in business service regulations and supervision (Mustilli and Pelkmans, 2013). In result, the high level of regulatory heterogeneity between the EU Member States exists and, along with the administrative obstacles, hamper the possibilities for efficient functioning of the Single Market in business services sector. Finally, as the European law regarding services does not assume harmonisation of regulations, the efforts of the European institutions must be directed towards the administrative barriers. And it seems that there is a considerable scope to reduce administrative obstacles. But it is highly probable that the last proposal of the European Commission on the Service e-card will not be accepted and implemented and scope of administrative barriers will stay unchanged.

Therefore taking all the above into consideration, we can conclude that the internal market in the business services sector is not functioning efficiently. It is also highly possible that in the coming years the situation will not change dramatically leaving the possibility of fulfilling and strengthening the internal market in the business services sector uncertain.

### **Abstract**

*The aim of the article is to show the specificity of the integration of the Eurasian Economic Union (EEU) on the example of the integration of the European Union (EU). The EEU is a relatively young grouping that was established in 2015 by Republic of Armenia, the Republic of Belarus, the Republic of Kazakhstan, the Kyrgyz Republic and the Russian Federation. Its creators try to give the Eurasian integration process a different direction in contrast to the structures that were created in the post-Soviet space. The EU was founded in 1993, but the beginning of the foundation falls on 1957, in which the treaties establishing the European Economic Community were signed by six founding countries: France, Germany, Italy, Belgium, the Netherlands and Luxembourg. The article presents the functioning of the EEU, its objectives, assumptions and forecasts for the further process of merging national economies.*

**Keywords:** Eurasian Economic Union, Europe Union, integration

**JEL Classification:** F15, F45, F02

### **1. Introduction**

The international integration processes main goal is a sustainable development of the states, elicitation of investment cooperation and joint projects (Pollack, 2001). The emergence of a new international organization, companies, as well as general import and export have a great impact on the economies of the participating countries. Foreign direct investment (FDI) can significantly affect the economic growth of developing countries through technology, knowledge and skills transfer (Deichmann et al., 2003).

The Eurasian Economic Union is an international organization of regional economic integration, within which the free movement of goods, services, capital, and labour is ensured. The Treaty on the Eurasian Economic Union was signed on 29 May 2014 in Astana. From 1 January 2015, a new stage in the development of Eurasian economic integration began. The introduction of the state of full functioning of the EEU allows not only for the consolidation of a de facto deeper level of economic integration in the Eurasian space but also confirms the legitimacy of the strategy for the further development of integration. The EEU's internal market comprises an economic area in which the free movement of goods, persons, services, and capital is ensured.

At present, the customs boundaries between members have been abolished in the EEU. Unified norms of the Customs Code, customs tariff, foreign trade system, customs regulations and technical regulations have been introduced (*Eurasian Economic Union (2018) access: 27/01/2018*). Integration within the scope introduced by the EEU eliminated the existing

barriers between economies, which allows the expansion of enterprises in new markets. In connection with the above activities, trade turnover and capital flows between enterprises are expected to increase. One of the effects of the formation of an integration group is to strengthen the internationalization of enterprises that take advantage of the opportunities to expand into new markets due to the elimination of existing barriers between economies. We can, therefore, expect an increase in trade turnover and capital flows (Daszkiewicz, 2016).

### **1.1 The Basic Principles of the EEU and EU**

The Eurasian Economic Union is established for the significant improvement of modernization, cooperation, for national economies competitiveness but also for the creation of conditions to raising the population living standards. The integration of production, labour, financial resources and science.

EEU is an international organization of regional economic integration that ensures freedom of movement of goods, services, capital, and labour, as well as coordinated and unified policy in economic sectors. The member states of the Eurasian Economic Union are the Republic of Armenia, the Republic of Belarus, the Republic of Kazakhstan, the Kyrgyz Republic and the Russian Federation. The creation of the Eurasian Economic Union was aimed at creating a bloc that would also be a partner and rival to the European Union and China (Michalik, 2015). It is worth noting, that the initiator of the creation of the Eurasian Union in 1994 was the President of Kazakhstan, N. Nazarbayev, who asked Russia to take over leadership in the economic union. It was only W. Putin, he became an appropriate partner for N. Nazarbayev to implement the integration project of the region (Gostomski and Michałowski, 2015)

The main objectives of the EEU are:

- creating conditions for the stable development of members economies in order to improve the living standards of their inhabitants;
- striving to create a single market for goods, services, capital and labour resources in the Union;
- comprehensive modernization, cooperation and increasing the competitiveness of national economies in the global economy.

The process of integration of European nations begun at the beginning of 20th century. In 1951, European countries began economic cooperation, the need arose to form a new grouping, a new common Europe. The EU was founded in 1957 by six countries: Belgium, France, Germany, Italy, Luxembourg and the Netherlands. In 2004 the EU took additional steps and the process of globalization has gained the new stage of development. Currently, the EU consists of 28 Member States. At the moment, the United Kingdom is still a member of the Union. There are several main goals that the EU pursued in the integration process:

- peacekeeping: EU values and the well-being of EU citizens, guaranteeing freedom, security and justice in an area without internal borders;
- economic integration :point of economic integration is the internal single market, established by the participating countries in order to create a unified economic territory that is not divided either by customs or trade barriers. At the heart of the single market are four such principles - free movement of goods, labour, services and capital. It is worth noting four important factors that are leading to these states: ensuring security, independence, welfare of society and the prestige of states. establishment of an economic and monetary union whose currency is the euro;
- promoting sustainable development based on sustainable economic growth and price stability, on a highly competitive market economy enabling full employment and social progress, and on environmental protection;

- political alliance: increasing economic, social and territorial cohesion and solidarity between Member States protection of rich cultural and linguistic diversity;
- social stability: combating social exclusion and discrimination, supporting scientific and technical progress.

## 2. Similarities and Differences of EEU and EU Integration Process

Comparison of integration processes leads to a comparison of the EU region and the region of the Eurasian Economic Union, taking into account historical time, the political and psychological context, approaches and models of integration in the context of the international environment. Integration processes reflect real economic and political trends in these unique regions of the world and create interaction between them. EU and EEU as continental international political institutions and the governing bodies of the EU and the EEU have their own powers as stipulated in the treaties and participate in the decision-making process and determine the main objectives of the Unions. It is worth noting that a political society and historical context is one of the most important roles in the integration process.

In 1994, the leader of the Republic of Kazakhstan, Nursultan Nazarbayev, proposed creating a truly working union of states in the Eurasian space, united by economic interrelations (Roberts and Moshes, 2016). In early 1995, the Republic of Kazakhstan, the Republic of Belarus and the Russian Federation signed the Agreement on the Customs Union aimed at removing obstacles to free economic interaction between economic entities of the parties, ensuring free trade and fair competition. In 1996, the leaders of the troika countries, together with the head of the Kyrgyz Republic, signed the Treaty on the deepening of integration in the economic and humanitarian spheres. On November 18, 2011, the Presidents of Russia, Kazakhstan, and Belarus signed the Declaration on Eurasian Economic Integration. By January 1, 2012, the legal framework of the Eurasian Economic Space (EES) - the market with 170 million consumers, free movement of goods, services, capital, and labour was formed (Tarr, 2016). The EES is based on concerted actions in key areas of economic regulation: macroeconomics, competition, industrial and agricultural subsidies, transport, energy, and natural monopoly tariffs. For the population and the business community, the gain from the EES was obvious. Entrepreneurs received equal access to the common market of countries, the ability to freely choose where to register their companies and do business, without undue restrictions, sell goods in any of the member states, and gain access to transport infrastructure. The creation and stage-by-stage debugging of the mechanisms of the work of the single market have become an important element of the plans of the countries participating in the Customs Union (CU) and the EES on the transition from the raw material economy to the innovative one. 2013 was one of the most significant periods in the improvement and development of Eurasian integration processes.

Integration of the European Union began in 1952, the European Union emerged as the European Coal and Steel Community (ECNU). It consisted of six founding countries: France, Germany, Italy, Belgium, the Netherlands and Luxembourg. The same countries were formed in 1958 by the European Economic Community (EEC) and the European Atomic Energy Community (EURATOM). But the European Community, as the association of the three communities calls itself since the 1960s, has always been calculated for the whole of Europe.

There are four stages in the expansion of the EU: expansion to the west in 1973 - accession by Great Britain, Ireland and Denmark, expansion to the south in 1981 and 1986 of accession - Greece, Spain and Portugal, expansion to the north in 1995 - accession by Sweden, Finland and Austria, extension to the east in 2004-2007 - the accession of Estonia, Latvia, Lithuania,

Poland, the Czech Republic, Slovakia, Hungary, Slovenia, Malta, Cyprus, as well as Bulgaria and Romania.

The Eurasian Economic Union began functioning on January 1, 2015. From October 2, Armenia became a full member, and on August 12, Kyrgyzstan joined. In October 2015, the presidents of the five Union countries approved the main directions of the economic development of the EEU until 2030 - an important document that determines the further coordination of national policies and ways to improve the competitiveness of the economies of the states of the Union. The effect of participation in the EEU by 2030 for member states is estimated to be up to 13% of additional GDP growth (Akhmetzaki and Mukhamediyev, 2017).

The EU is based on the principle of solidarity: the more economically developed member states help in the economic development of developing member states so that they are able to compete in the single European market (Jachtenfuchs, 2001). The EU has completed the process of monetary union and political union. Language factor: the method of translating accepted acts and all necessary documents into all languages of member states, but the process is not effective because it takes a very long period and a lot of financial resources for translations. There is an inter-parliamentary structure that represents the citizens of the EU. The main political institutions influencing the European integration process are NATO, the OSCE, the Council of Europe and transnational corporations. It is characterized by an independent common foreign policy and policy in the field of defence and security.

EEU uses a multi-rate integration method, counts on the economic readiness of member states for further integration. Like the EU, I have fulfilled all the necessary integration phases: a free trade area, a customs union, a common domestic market, an economic union. It has a high degree of dynamism because it takes into account the experience of the EU and other regional associations. Authors Mishalchenko and AV Izotov (Мишальченко and Изотов, 2014) believe that the role of a certain institutional "launching pad" for the start of important integration projects in Russia, Belarus and Kazakhstan was played mainly by international organizations: the CIS, EurAsEC, the Union State of Russia and Belarus (Anonymous, 2016). S.Yu. Glazyev notes that the Eurasian integration is based on the principle of treating the partner as an equal, respecting the voluntariness and mutual respect for the spiritual values and cultural identity of the united states with equal rights in making supranational decisions (Глазьев, 2014). There is a process of strengthening the sovereignty of the national member states on the basis of equality to the partner as an equal, the observance of voluntariness and mutual respect for the spiritual values and cultural identity of the unifying states with equal rights in making supranational decisions. The language factor is a common Russian language for all, which creates an effective bridge in the post-Soviet space, economic interaction, and is an important geopolitical factor. Decision-making procedure: implemented in each governing body on the basis of consensus, unlike the EU (Kirkham, 2016). "The Eurasian Economic Union represents a model of a supranational association that can become one of the poles of the modern world and at the same time play the role of an effective liaison between the Asia-Pacific Region and Europe".

Accordingly, to the integration process of EEU it shows a promising effect on economies of individual union members (Barakhvostov and Rusakovich, 2017). In comparison with January 2016 – February 2018 the economic characteristics have changed (Pridachuk and Tolstel, 2016). The GDP has increased from 4% to 15% (Table 1). The most significant increase of GDP was achieved by Russia 15.24% followed by Kyrgyzstan 14.28%, Kazakhstan 10.17%, Armenia 7.89% and Belarus 4.57%. Standard of people living also increased, what can be observed on the example GDP – per capita, which was 17.72% - Russia, 8.82% - Kyrgyzstan, 8.33% - Armenia, 5.66% -Kazakhstan and 4.49% - Belarus. In case of inflation rate, a

significant decrease was observed up to 72.72% in Russia and 66.07% in Armenia, next 53.08% and 46.66% in Kyrgyzstan and Belarus, respectively. Only in the case of Kazakhstan, the inflation rate increased by 35.84% due to the increasing prices of goods and services. The number of economically active people also increased, which results in the drop of the number of an unemployed rate in Belarus 28.57%, Kyrgyzstan 10% and Kazakhstan 3.92%. Slight increase was observed in Armenia 1.12% and a significant increase in Russia as much as 13.64%.

**Table 1: Characteristics of the EEU Member Countries (at 25.02.2018)**

Country	Population, mln	GDP, billion US dollars	GDP - per capita, thousands US dollars	Inflation rate, %	Unemployment rate, %
<b>Russia</b>	146.9	4000	27.9	4.2	5
<b>Belarus</b>	9.5	175.9	18.6	8	0.5
<b>Kazakhstan</b>	18.2	474.3	26.1	7.2	4.9
<b>Kyrgyzstan</b>	6.2	22.64	3.7	3.8	7.2
<b>Armenia</b>	3.0	27.21	9.1	1.9	18

Source: CIA World Factbook (2018)

Comparison of characteristic economic indicators of the EEU Members to founding Members Countries of Europe Union they show significant differences in the wealth of these countries (Table 1). In case of GDP only Russia can compare with EU member countries, where the rest EEU Members have several times lower to EU Member countries. Also, the GDP – per capita and inflation rate are quite significant differences. However, the unemployment rate is lower for EEU than UE, which can be caused by several factors; immigration, the crisis in the euro area or leaving the Union by Great Britain (Scharpf, 2010). Moreover, should be taken into account that EEU is still very young Union which is created by countries which were historically dependent on Russia.

**Table 2: Characteristic of the EU Founding Members Countries (at 25.0.2.2018)**

Country	Population, mln	GDP, trillion US dollars	GDP - per capita, thousands US dollars	Inflation rate, %	Unemployment rate, %
<b>Belgium</b>	11.5	0.53	46.3	2.2	7.3
<b>France</b>	67.1	2.8	43.6	1.2	9.5
<b>Germany</b>	80.6	4.2	50.2	1.6	3.8
<b>Italy</b>	62.1	2.3	38	1.4	11.4
<b>Luxembourg</b>	0.6	0.06	109.1	1.2	17.4
<b>Netherlands</b>	17	0.9	53.6	1.3	5.1

Source: CIA World Factbook (2018)

**Figure 5: Represent the Total Value of Export Operations of the EEU Member States in Mutual Turnover for 2016 in mln USD**

Source: Own elaboration based on: Евразийскаяэкономическаякомиссия (2017)

According to the Eurasian Economic Commission, the volume of EEU transactions in 2016 compared to 2015 increased from 13.6 to 14.2%, which is a very positive phenomenon (Figure 1). The turnover in the EEU is USD 42,536.40 mln. Table 1 shows the volume of trade between countries, members of the EEU. The mutual turnover is as follows: Armenia - Belarus - 36.1 mln USD, Armenia - Kazakhstan - 6.3 mln USD, Armenia-Kyrgyzstan - 1 mln USD, Armenia - Russia - 1 328,20 mln USD, Belarus - Kazakhstan - 395 , USD 6 mln, Belarus - Kyrgyzstan - USD 52 mln, Belarus - Russia - USD 25,965 million, Kazakhstan - Kyrgyzstan - USD 651.2 mln, Kazakhstan Russia - USD 12 936.10 mln, Kyrgyzstan - Russia - PLN 14,890 mln USD.

### 3. Conclusion

The European and Eurasian region is truly unique in terms of historical experience and specifics. The EU has achieved the highest degree of integration development, its experience is a measure of the effectiveness of integration and also an example on which the EEU should rely. The legal base of the EEU implies reaching a high level of integration of this Union. To achieve a high level of integration, the EEU also presupposes the level of the "energy union". Also the transport network and infrastructure are the main elements for deepening integration. The Eurasian integration process presupposes the possibility to go beyond the post-Soviet space. Mutual understanding is necessary for EU and EEU integration projects. The EU should perceive the Eurasian integration process as an integration process of independent states without advancing the idea of Russian imperialism.

Vladimir Putin's many announcements about Eurasian integration have become part of the actual policy of states and are the most advanced integration structure that was created after 1991. Its creators try to give the Eurasian integration process a different direction in contrast to the structures that were created in the post-Soviet space. Russia's vast advantage makes it

difficult to guarantee the interests of other entities forming a new grouping, although the first years of the EEU operation confirmed that it was not possible to find a balance on economic and political issues because Russia was the beneficiary of integration. Another problem is the rapid construction of Eurasian institutions: within five years (up to 2015). They intend to achieve a result for which the EU has worked for several decades.

To some extent, the EEU is a project referring to the Soviet past, although it benefits from the experience of other integration groups. The EEU is a challenge for the enlargement processes that have been ongoing for over twenty years on the European continent, so far they have not been allowed.

### **Abstract**

*This paper examines the factors of development of green entrepreneurship in European Union through domestically developed standards and international frameworks, which arises because of the deepening of European integration, they also can bring profits for new enterprises and European economy. These tendencies develop towards globalization, justice and solidarity as a model of material extensive and sustainable development. This paper aim is to identify what is green entrepreneurship and to list the two groups of selected indicators which measure the shape and its unique character among selected countries as the important tool which may support European integration process. The Hellwig's pattern method was used as a main analysis method in this paper. The comparison of two types of indicators reveals a group of European countries where green entrepreneurship development is easier than in other member states of EU.*

**Keywords:** *European integration, green economy, green jobs*

**JEL Classification:** *F15, F64, J6, O13, Q54, Q56*

## **1. Introduction**

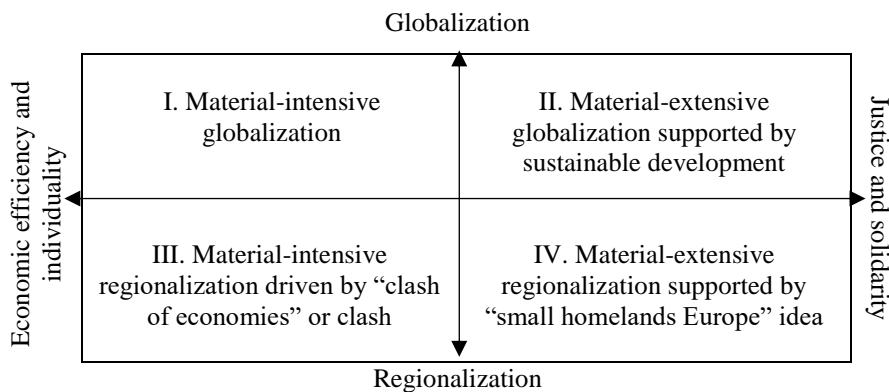

Nowadays European Union integration requires that environmental factors are taken into account in the formulation and implementation of all sectoral policies (Šotkovský, 2012). Integration also involves a cross-sectorial dimension since environmental problems such as climate change, biodiversity protection and water management are related to the multiple causes and sources of pollutant emissions and natural resource management across sectors (Liberatore, 1997). European integration is a process which depends on both external and internal factors relevant for moving towards sustainable development which European Union decided to achieve. The entrepreneurship can be appointed as the most important internal factor which influence directly labour market and consumption in the European Union. This entrepreneurship can be aimed on green development and measured by sustainability and durability indicators. Therefore, this paper attempts to discuss current notions and practices on integration in the EU, including their relationship with the concept of green and sustainable development in the entrepreneurship sphere. The aim of the paper is to examine the factors of development of green entrepreneurship in selected countries of European Union through domestically developed standards and international frameworks.

The first section of this paper presents idea shift towards material-extensive and sustainable model of development. Then green entrepreneurship and green job definitions are presented. Finally, the main problem is formulated as lack of sustainability indicators which may help to assess positive environment for green entrepreneurship in European integration context. Then the analysis of selected traditional and sustainability indicators is performed to draw a set of conclusions. Green entrepreneurship can form an integral part in the fight against youth unemployment due to the low entry-level requirements for young people in many sectors and their generally strong interest in innovative business solutions and sustainability considerations.

## 2. Green Development Ideas in European Integration Context

Europe's future depends, in wider context, on sphere of ideas concerning fundamental values and symbolic references. The problems of EU integration are related to a change in modern economy and labour market (Sulich and Rutkowska-Podołowska, 2017). Europeans' key concerns are about choosing the right set of values, one being social solidarity – the other, assuring prosperity to the most affluent groups of citizens. Therefore, the idea of support green entrepreneurship seems to be right way to achieve sustainable growth (Kasztelan, 2016). The shift from brown economy (model I or model III) to green economy is visible and is related to a shift to second model (II) proposed on Figure 1.

**Figure 1: EU Development Models**

Source: author's elaboration

It is possible to indicate some EU countries which may be assigned to the one of models presented on Figure 1. Moreover, the European Union has a set a goal to be a low-carbon economy and the key instrument for reducing greenhouse gas emissions (Bocora, 2012). The aim of this action is to motivate companies to reduce emissions and achieve minimum impact on social welfare and natural environment (de Bruin, 2016). A concomitant problem is the environmental sustainability of rapid economic growth: the location of waste facilities; the quality of water for drinking; planning in rural areas; and the high dependence on fossil fuels are all issues facing contemporary European society (Hon and Honová, 2012). Therefore, some of the European Union member states can be seen as leaders of the shift towards green economy, due to their natural capital.

Nowadays, natural capital is seen as a key element of socio-economic development (Bocora, 2012). Environmental resources and values are important factors in achieving not only green

development but also competitive advantage of small and medium-sized enterprises in the EU (Corbett and Montgomery, 2017). Moreover, small and medium-sized enterprises are the backbone of most of European countries economies, providing high levels of employment and contributing extensively to GDP growth (Sulikova et. al., 2015; Zhang and Walton 2017). Entrepreneurship results in wide range of innovation as well as sustained economic and social development (Kasztelan, 2016; Kryk 2016). Created by green entrepreneurs, green jobs provide a new source for starting and sustaining, green economy.

### **3. Green Entrepreneurship and Green Jobs Definitions**

Green entrepreneurship can be defined from two perspectives related to the output (products and services) as well as the process (or production) of an economic activity (ILO [online], 2017). Entrepreneurs can enter into an overtly 'green' business sector, providing green and environmentally friendly products and services. Alternately, green entrepreneurs can provide their products or services through an environmentally friendly process or with the help of clean technologies. Usually, green entrepreneurs consider both aspects in their activities, creating additional decent employment through the use of more environmentally friendly processes, while reducing the overall environmental impact as a result of people or companies using the final product or service (ILO [online], 2017).

Originating mainly from a level of technical innovation such as pollution reduction, clean production processes and resource efficiency, green entrepreneurship goes beyond the narrow technology-based aspects of doing business (Kryk, 2016). It can nurture a culture of lifecycle-based thinking and stimulate green innovation at the societal level. In doing so, green entrepreneurs create a shift in peoples' mindsets towards greener thinking and increased demand for green products and services, boosting the dual effect of employment and environmental gains (Schaper, 2005; Zhang and Walton, 2017).

Green jobs are places of employment that contribute to protect preserve or restore the natural environment (Rutkowska-Podołowska et al., 2016). According to United Nations Environment Program (UNEP) green jobs can be defined as work commenced in various sector of economy which contribute to ecosystem and biodiversity protection, but also is a guarantee of decent wage (UNEP, 2008; Kryk, 2016; Rutkowska-Podołowska and Sulich, 2016).

### **4. Problem Formulation and Methodology**

Environmental factors have to be taken into consideration in the formulation and implementation of the policies that regulate economic activities and other forms of social organization. Therefore, a new model of development can be achieved, a model that can be environmentally and socially sustained and durable (Corbett and Montgomery, 2017). It is not possible to indicate which of these business environment factors (Table 1) is more important, because both influence to each other. This is a result of the increasing interaction between the previously seen as separate spheres of the economic activity (Šotkovský, 2012). In turn, it is to be expected that environmental policy will be changed as a result of the growing interdependencies between different sectors of business and related to them policy agendas of environmental protection, economic growth and activities with major economic as well as environmental impacts, such as agriculture and transport (Rutkowska-Podołowska and Popławski, 2016). An important aspect to be considered is the fact that integration can result either in the strengthening of environmental considerations and priorities or in their dilution within other policies. Recently, governments have started paying close attention to how business can contribute to society through development of clean production, introducing green jobs and corporate social responsibility activities, particularly in its environmental aspect

(Adámek, 2016). The European Union in its strategy Europe 2020 has set a goal to achieve – sustainable growth as a part of low-carbon and green economy (Hon and Honová, 2012). Therefore, the aim of this paper is to examine the factors of development of green entrepreneurship in selected countries of European Union through domestically developed standards and international frameworks.

Although there are multiple of indicators which can describe green competitiveness of 20 selected from EU-28 countries (Kasztelan, 2016; Penalvo-Lopez, Carcel-Carrasco et al., 2017). They are completely different in case when companies are subject of comparison. Then only few indicators are essential for assessment of green entrepreneurship and its influence on labour market using Hellwig’s pattern model. Sustainability indicators were initially selected based on Eurostat data for small and medium companies. The reference years 2010-2016 were chosen due to data availability. Presented in Table 1 sustainability indicators attempt to meet three criteria: substantive, formal and statistical. Next step was to check if acknowledged indicators meet statistic criteria – the coefficient variation is greater than 10%. Therefore, 3 traditional indicators (with symbol  $x_i$ ) and 5 sustainable indicators (symbol  $y_i$ ) were listed in Table 1. Among the selected indicators only one ( $x_1$  - unemployment rate) was considered to be better if smaller, whereas the rest were regarded as larger-the better characteristics having positive impact on the measure. Table 1 also consists possible interpretation of traditional and sustainable indicators.

**Table 1: Two Groups of Economic Indicators of Green Entrepreneurship Development**

Indicator symbol	Traditional indicators	Indicator symbol	Sustainability indicators	Interpretation
$x_1$	Unemployment rate (% of total population)	$y_5$	Variability of skill levels required for jobs	Resilience of the job market
$x_2$	Employment rate (% of total population in age 20-64)	$y_5$	Number of diversity and vitality of local job base	
		$y_5$	Number of green jobs (EGSS)	Ability of the job market to be flexible in times of economic change
$x_3$	Number of births of enterprises (in thousands)	$y_5$	Number and variability in size of companies	
		$y_5$	Number and variability of industry types	

Source: Sulich and Rutkowska-Podołowska (2017) and Eurostat (2017)

To check of all selected countries the Hellwig’s pattern method based on traditional indicators measured by central statistical offices was suitable (Kasztelan, 2016), whereas to compare organisations in the EU and asses their impact on labour market the new set of sustainable indicators have to be taken into account (Eurostat [online], 2017). All steps of Hellwig’s pattern method were applied, to construct the systematic variables. Only the  $x_2$  indicator was transformed according to the formula:

$$x_{ij} = \frac{1}{x_{ij}} \tag{1}$$

The other features were standardized according to the formula:

$$z_{ij} = \frac{x_{ij} - \overline{x_{ij}}}{s_j}, \tag{2}$$

where  $i$  – is object number,  $j$  – feature number,  $s$  – is standard deviation. Such transformed features were subject of calculations of taxonomic distances between the investigated factors

values and reference model (Penalvo-Lopez, Carcel-Carrasco et al., 2017). This distance was calculated according to the formula:

$$d_i = \sum_{j=1}^m |z_{ij} - z_{0j}| \quad (3)$$

The calculations were performed also for the indicators marked as  $y_i$ . Obtained  $d_i$  values were used to compute Hellwig's synthetic measure of green development:

$$z_i = 1 - \frac{d_i}{d_0} \quad (4)$$

The  $z_i$  indicator assumes values within the range [0;1], whereas values closer to the model and are associated with high level of the investigated object. Obtained values  $z_i$  were arranged in linear manner in four groups:

$$1. \quad z_i \geq \bar{z} + s_z \quad (5)$$

$$2. \quad \bar{z} \leq z_i < \bar{z} + s_z \quad (6)$$

$$3. \quad \bar{z} - s_z \leq z_i < \bar{z} \quad (7)$$

$$4. \quad z_i < \bar{z} - s_z \quad (8)$$

Where:  $\bar{z}$  is arithmetic mean,  $s_z$  – standard deviation. Then values of  $z_i$  indicators were calculated for selected EU countries based on traditional and sustainable indicators. Stimulating green entrepreneurship in the European Union requires an approach combining interventions at different levels, which can be described by three main group factors Table 2.

**Table 2: Factors of Green Entrepreneurship for Selected 20 Member States of EU-28**

<b>Traditional indicators</b>	<b>Mean</b>	<b>Minimum</b>	<b>Maximum</b>	<b>Standard deviation</b>	<b>Coefficient variation [%]</b>
Unemployment rate	6,4	2,6	17,3	3,02	47,2
Employment rate	33,2	3,2	77,0	17,91	54,0
Births of enterprises [thousands]	43051	3359	30551	41726,32	96,9
<b>Sustainability indicators</b>	<b>Mean</b>	<b>Minimum</b>	<b>Maximum</b>	<b>Standard deviation</b>	<b>Coefficient variation [%]</b>
Variability of skill levels required for jobs	1,7	0,3	4,0	1,1	64,5
Diversity and vitality of local job base	2,9	0,6	10,6	2,8	97,5
Number of green jobs (EGSS)	2353,0	268,0	9410	2281,7	97,0
Variability in size of companies	27,0	6,6	68,1	17,8	65,9
Variability of industry types	18,7	8,0	38,0	8,0	42,7

## 5. Problem Solution

Based on selected indicators: traditional and proposed by Eurostat sustainable development indicators selected 20 countries of EU-28 were assigned to four different groups which were created based on  $z_i$  - synthetic measure of green development conditions for green entrepreneurship. According to obtained results traditional indicators do not provide satisfactory answer in which country green entrepreneurship has a chance to thrive.

**Table 3: Classification of 19 EU Member States According to Value of the Synthetic Measure for Traditional and Sustainable Development Indicators**

Group number	Traditional indicators	Sustainable development indicators
I	Italy, Poland, France, Spain	Finland, Denmark, Sweden, Germany, Austria, Estonia, Latvia,
II	Romania, the Netherlands, Portugal, Belgium, Denmark,	the Netherlands, Belgium, France, Czech Republic, Slovakia, Slovenia,
III	Bulgaria, Hungary, Slovakia, Czech Republic, Latvia,	Poland, Hungary, Italy, Spain, Portugal,
IV	Finland, Sweden, Slovenia, Germany, Austria, Estonia	Romania, Bulgaria

Source: authors' calculations based on 2010-2016 data from Eurostat.

Presented in Table 3. Group countries are similar to results obtained by Kasztelan in area of selected traditional indicators (Kasztelan, 2016), however results obtained in column of sustainable development indicators are different and indicate that some countries create better conditions for green entrepreneurship. Some of them also have green competitive advantage like Finland or Denmark.

**Table 4: Groups of Green Entrepreneurship Factors**

Factors Group	Description
<b>Culture</b>	Nurturing a green business culture and raising awareness amongst entrepreneurs about opportunities arising from environmentally friendly business models.
<b>Policy</b>	Creating an enabling environment which promotes and encourages green investments and entrepreneurship.
<b>Funding</b>	Supporting new and emerging entrepreneurs through the provision of business development services and other financial and technical support schemes.

Source: ILO (2017)

Presented in Table 1 sustainable development indicators can be appointed as related to the culture factors of green entrepreneurship supported by each country individual green competitiveness (Table 4). Cultural factors seem to be more important than other two groups of support offered in countries grouped in first group, whereas traditional indicators can be related to policy and founding factors group. Analysed selected factors presents 20 selected countries which may be ranked due to their leadership role in green entrepreneurship and leaders of the European integration - group I of sustainable development indicators (Table 3).

## 6. Conclusion

Green entrepreneurship can provide new employment opportunities to workers who are set free during the restructuring towards a greener economic model. Implementation of this model brings four facts which have to be emphasized as follows: green entrepreneurs are indispensable for employment creation and GDP growth; SMEs are highly interlinked within value chains, creating significant spill-over effects; green entrepreneurship can best be supported through interventions at various levels, using a broad choice of instruments; finally the youth can be well targeted, since entry requirements are low and willingness for innovation is high. Moreover, sustainable development indicators presents involvement of some member states in European integration expressed in cohesion in environmental policy and reflect better shift to green model of EU development. Finally the relations between so described areas of European integration indicates that further research in this topic is required.

European integration is still in its beginning, hence even now the political elites are strongly dependent on their national voters, who decide their position. Moreover, one can forecast that this situation will not soon change, as politicians, very much like voters, will perceive integration through the perspective on national benefit. It was aim of this paper to spot some countries as examples of cooperative fronts among European entrepreneurs in relation to Europe's future. One of the most important factors conditioning the future of the EU is its economic competitiveness coming from green entrepreneurship. Green businesses are gaining popularity as more opportunities arise for eco-entrepreneurs to invest in which will be a topic for further research as well.

### **Abstract**

*This paper examines the impact of institutional flexibility and institutional quality and their interactions on economic performance. Studies show that while institutional quality reduces transaction market costs, this leads to an immediate but short-term growth in economic growth. On the contrary, the increase in institutional flexibility leads to a steady growth. This paper suggests that past institutional studies place too much emphasis on the stability of institutional settings. The aim of the research is to provide new insights on the issue of institutional flexibility and quality in terms of economic performance. The analytical part of research focuses on the characteristics of the EU states in the period 1996-2016. The results show significant effects of institutional flexibility and quality measures on economic performance.*

**Keywords:** *economic performance, European Union, institutional environment*

**JEL Classification:** *E02, O10, O43*

### **1. Introduction**

Institutions and their impact on the economy have been a subject of economic studies already many years. There are many studies currently underway to help understand the mechanism of economic growth. Determinants of economic growth that reflect the quality of institutions have long been important indicators. Institutional flexibility has only recently come to attention. Earlier studies had a simple assumption regarding the stability of the institutional environment. These studies (such as Acemoglu et al., 2001) point to a positive link between economic growth and institutional stability. However, later studies (such as Davis, 2010) show that while institutional quality reduces transaction costs on the market, it leads to an immediate but short-term growth in economic growth. On the contrary, the increase in institutional flexibility leads to a steady growth. Exploring these effects is particularly important for the continuation of European integration, as the European Commission (2012) stresses the need to continued reforms that can be postponed due to the fear of a negative effect caused by institutional instability.

This paper suggests that some past institutional studies place too much emphasis on the quality of institutional settings. Research shows the significance of both of these characteristics (both quality and flexibility (instability)). The goal of this paper is to investigate the impact of selected institutional indexes (in terms of both quality and flexibility of institutional environment) and their interactions on economic growth in 28 member states of the European Union. The analytical part of research focuses on the institutional characteristics of the EU

states in the period 1996-2016. More precisely, six institutional indexes from World Government Indexes is taken into account. To determine the impact of these institutional indexes on economic growth a panel data analysis, based on a growth model, is provided for the examined period. The analysis in this paper shows both influences of institutional quality and flexibility on economic growth.

The structure of the paper is as follows. After a short introduction, the second section provides an overview of the theoretical relations between institutional quality, institutional flexibility, and economic growth. The second part of the section is devoted to a description of methodological issues. The empirical results of the model derived in the second section are consequently presented (in the third section). The last section summarizes main findings.

## **2. Theoretical Background and Methodology**

Institutions and their impact on the economy were investigated in many studies. Many of them were inspired by the insights of Douglas North (1991). These insights were later applied in a variety of econometric studies that confirmed the importance of the institutional environment as an important determinant of economic growth (e.g. Barro 1996; Knack and Keefer, 1995). Many of mentioned studies were focused on positive impacts of institutional quality to economic growth. However, the crucial role of institutions was found not only regards the economic growth. Some studies were also focused on the relationship between quality of the institutional environment and innovational performance (Tebaldi and Elmslie, 2013).

On the other hand, there are not so many studies focused on institutional flexibility. One of the most important research in this field is study by Lewis S. Davis (2010), who developed a theoretical model of institutional flexibility and economic performance. According to this work, while institutional quality plays an important role in the short run, institutional flexibility plays an irreplaceable role, especially in long-run economic performance. It can be stated that notion of efficient institutions is based on circumstances because as conditions change over time, 'what are good institutional forms at one stage are no longer appropriate at others' (Storper, 2005). The institutional environment was considered as important determinant also for economic resilience (Melecký and Staničková, 2015) and in connection with technological resilience (Balland, Rigby and Boschma, 2015). Last mentioned study has proven the innovative capability of US cities and shows that cities with greater institutional flexibility are also less likely to fall into so-called technological crises (their results shows that an increase in the institutional flexibility of cities significantly lowers the risk of entering a technological crisis).

### ***2.1 Theoretical Channel Between Institutional Flexibility and Economic Growth***

One of the main criticism focused on the research of the institutional environment and its impact on economic growth is the lack of a dynamic perspective. Many studies highlight the stability of institutions as the only aspect of the institutional environment (for example, Acemoglu et al.; 2001). Still, in the literature, a deviation from a static point of view can be found. For example, Abramovitz (1986) notes the country's ability to adopt new foreign technologies, while noting that while country institutions can be well designed, they may not have the ability to adapt to new requirements. The ability of the policy and the legal system to respond to the changing institutional demands of an evolving economy thus appears to be a longer-term aspect of the institutional environment than the very quality of economic policy or trade laws.

The positive effect of institutional flexibility is explained by two basic mechanisms. The first is the idea that countries need to endure a period of change when implementing reforms to improve institutional quality. This necessarily leads to a temporary increase in institutional instability. This idea is in line with Hayek's (Hayek, 1973) explanation of institution-building, in which there is a need for experimentation with institutional settings to achieve growth. Without the trial-and-error process, political decision-makers often cannot get information on how concrete reforms work. The second idea is Olson mechanism (Olson, 1982). This explains negative side effect of excessive institutional stability, with the anticipated increase in influential groups that, by tracking their own interests, contribute to reducing the rate of economic growth. Conversely, achieving the necessary degree of institutional instability (or flexibility) weakens the influence of interest groups (and their rent-seeking activities).

## **2.2 Methods and Data**

In this section, the baseline model and dataset used to evaluate the impact of selected institutions measures is described. Following similar studies (e.g. Berggren et al., 2015) a panel regression analysis is used to answer the research question: what are the effects of institutional flexibility and quality on growth. In order to determine the impact of institutional flexibility and quality on economic growth a panel data method especially regression models with time- and country-fixed effects are employed. The dependent variable is the annual growth rate of GDP per capita in purchasing power standards. However, here is the question about correct specification of growth regression especially the question about what may be control variables in it. Unfortunately, there is no complete agreement on what control variables to use in such growth models (there are many studies about control variables in growth regressions, see, e.g. Barro (1996)). Similarly to mentioned studies, a standard set of control variables is included (i.e. initial GDP, government expenditures as a share of GDP, gross fixed capital formation as a share of GDP (GFCF) and labour force growth (measured as annual growth of economic activity rate). All four control variables were acquired from Eurostat (Eurostat, 2018)). Although the interdependence of variables is probably much more complex, economic growth is perceived as a result of activities, while other variables in the study are perceived as driving forces.

Table 1 gives variable description and sources for the data used in regression analysis (except mentioned control variables) so that variables measuring institutional quality and instability are described there. In order to use suitable institutional quality and institutional flexibility measures, World Government Indices (WGI) is employed (Kaufman et al., 2010). The Worldwide Governance Indicators (WGI) is a research data set that summarizes views on the quality of governance provided by a large number of respondents from businesses, citizens and expert surveys in industrialized and developing countries. This data set is suitable for this analysis because it is based on hundreds of surveys. The mentioned dataset consists of six different indexes (see Table 1) which covers six different institutional areas.

**Table 1: Description and Sources of Variables Based on WGI**

Variable	Source	Description
VA	WGI	Voice and Accountability
PLST	WGI	Political Stability and Absence of Violence/Terrorism
GOEF	WGI	Government Effectiveness
RQ	WGI	Regulatory Quality
RL	WGI	Rule of Law
CC	WGI	Control of Corruption
GovernanceCV	WGI, own	Coefficient of variation across periods of PFA scores
GovernanceQ	WGI, own	Average of PFA scores across a five-year periods
GovernanceTR	WGI, own	Trend of PFA scores across a five-year periods
CV_	-	Coefficient of variation across periods of WGI indexes
avg_	-	Averages of given WGI indexes across periods

Source: Own construction

This data are available for 28 member states of the European Union within period 1996 – 2016 (Austria, Belgium, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Netherlands, Poland, Portugal, Romania, Slovakia, Slovenia, Spain, Sweden, United Kingdom).

The choice of the period was determined by the availability of data for the given period. Indicators are used both separately and also in aggregated form. In order to get not arbitrary aggregation principal factor analysis (PFA) is performed. This approach could be difficult regards to interpretation of calculated factor, but in our case, PFA gets only one easily interpretable factor. This factor (or main component) is correlated with all six WGI indexes and cover approximately 80 % of dataset variation. For purpose of this paper is this factor named “Governance quality”. To construct measures of quality, five averages for five-year periods 1996-2000, 2000-2004, 2004-2008, 2008-2012, 2012-2016 was calculated for each country. Institutional flexibility is measured by the coefficient of variability calculated for given country within the same five five-year periods. Each of this variable (except initial GDP) is calculated as average for each a five-year period). Initial GDP corresponds to the first of each five-year period.

In the following, the regression analysis is employed as in the equations below, where:

- X stands for control variables,
- Q stands for a set of measures of quality of institutions calculated as average,
- $CV_q$  capturing institutional instability as the coefficient of variation of Q across each five-year periods,
- GovernanceCV is the coefficient of variation across a five-year period of PFA score,
- GovernanceQ stands for an average of PFA score across a five-year periods,
- GovernanceTR is a trend based on “Governance quality” factor (described below),
- $\varepsilon$  stands for error term.

Then first regression equation is as follows:

$$gGDP = \alpha + \beta X + \gamma CV_Q + \delta Q + \varepsilon \quad (1)$$

When interpreting the effects of institutional flexibility, interactions of institutional quality and flexibility have been considered as important aspects (e.g. Brambor, Clark and Golder, 2006). In order to concern this approach, interactions between quality and flexibility of each WGI index is included in regression analysis. Another often-neglected aspect is an evaluation of different institutional trends. That is why the trend of factor “Governance level” is calculated based on the beta coefficient of regression line constructed for each five-year period from PFA scores. This trend evaluation is categorical value and separate positive trend (trend=1, above the 75<sup>th</sup> percentile of beta coefficients); negative trend (trend=-1, below the 25<sup>th</sup> percentile of beta coefficients) or roughly constant trend (trend=0, between first and third quartile).

The second and third regression equations are as follows:

$$gGDP = \alpha + \beta X + \gamma [CV]_Q + \delta Q + \text{interactions of CV and Q} + \varepsilon \quad (2)$$

$$gGDP = \alpha + \beta X + \delta \text{GovernanceCV} + \gamma \text{GovernanceQ} + \varphi \text{GovernanceTR} + \varepsilon \quad (3)$$

### 3. Empirical Results

Using the data and concept of regression models described above, series of panel regression with fixed effect was performed. The empirical results of panel regression analysis for the baseline model (1) and its extensions (2) and model based on aggregated data (3) are reported in Table 2. The signs of control variables are as expected but not all of them are significant. GDP is strongly significant. This result illustrates the strong convergence effects that could be expected in relatively similar countries. Government expenditures are also negatively and significantly related to economic growth. Conversely, Gross Fixed Capital Formation is insignificant. Regarding the institutional variables, only in the case of the second model (2) two of the institutional flexibility measures (CV\_RQ, CV\_RL) have statistically significant impact on economic growth, however, with different signs. While variability of the Regulatory Quality (which reflects the ability of the government to develop desired policies permitting private sector development) has a positive effect, variability of the Rule of Law (which reflects perceptions of the extent to which agents have confidence in the rules of society) is negative. The first finding is in compliance with assumptions about the Olson mechanism and Hayek notion. The latter finding is similar to other studies, but there is a question about the explanation of the negative sign.

Another strange result, in contrast with expectations, was found in the case of the first model (1), where one of the institutional quality measures (avg\_RQ) has negative effect on economic growth (but this result is not so strange in comparison with similar findings (e.g. Berggren et al., 2015)). The results of the model based on aggregated data (3) approve the importance of neither flexibility nor institutional quality based on aggregated PFA scores (trend as well as). The second column of Table 2 includes also the estimates of interactions between variability and quality of given WGI indexes. The results show that only two pairwise interactions, CV\_RQ x avg\_RQ and CV\_RL x avg\_RL, significantly explain economic growth. The second one refers to the following relation: the higher the “Rule of Law” is conditioned by institutional flexibility, the greater the effect it has on economic growth. It is, however, the opposite, when the effect of quality is unconditional by instability. This result shows that the quality of the institution environment measured by Rule of Law WGI index does not affect growth when it stands separately. Effect on economic growth can only be seen in interaction, which is entirely in line with similar studies. In addition, it is evidence for the effect of the so-called Olson

mechanism or the Hayek mechanism. Opposite result is in the case of the first pairwise interaction (CV\_RQ x avg\_RQ) - effect is negative.

#### 4. Conclusion

In this paper, we were interested in the question whether the institutional flexibility and quality of the European countries could be related to the economic growth in the member states. The empirical results based on a panel of 28 European countries observed across five five-year periods between 1996 and 2016 suggest significant effect of interaction of institutional quality and flexibility on growth (in the case of Regulatory Quality and Rule of Law indexes – CV\_RQ x avg\_RQ and CV\_RL x avg\_RL). However, in contrast with the theory, first mentioned relationship is negatively related with growth. The same significant result (only with opposite sign) was found in the case of estimating separate flexibility effect (i.e. coefficients of variability of Regulatory Quality (CV\_RQ) and Rule of Law (CV\_RL) indexes).

With regard to indicators reflecting only institutional quality, except for one case, all estimates were insignificant. The only case concerns the Regulatory Quality Index (avg\_RQ), which, however, also in contrast with the theory, shows negative dependence with growth. On the other hand, this surprising result is in line with the results of other study (Berggren et al, 2015), where the quality of legal-administrative institutions is negatively associated with growth. Results also show the interdependence of institutional flexibility and quality (especially in the case of interaction CV\_RL x avg\_RL this is in line with the Olsonian idea that stable institutions can simplify influence of interest groups on the political process and create policies that are harmful to long-term growth).

Without overstating the causal relationship between flexibility and economic growth (because this issue could be answered only with longer time series), two results deserve to be emphasized. First, at least in the case of the CV\_RL x avg\_RL beneficial association between growth and high institutional quality is not weakened by flexibility, but instead seems to be growth-promoting. In other words, there is no clear evidence that the short-term instability created by reforms impedes the positive effects of these reforms. This is very important from the point of view of European integration because it seems irrelevant to expect negative effects in the case of rapid reform compared to the slow implementation of reforms. Second, while the results should be particularly carefully interpreted, at least part of them are compatible with the idea that institutional instability can mitigate negative growth effects of Olsonian sclerosis and institutional adjustments in the spirit of Hayek could have a growth-enhancing effect. European data, therefore, indicate that it seems that the simplifying view that instability of institutions is always detrimental to growth has not been the case for European Union over the past two decades. In upcoming studies, it could be interesting to re-estimate the growth equation using different data sets of institutional quality to find out how the influence of different institutional measures varies and solve the causality issue.

### **Abstract**

*The primary objective of this study is to determine the impact of firm size on the innovation activity on the example of integrating still and parallel the developing country. In contrast to existing innovation policies in more integrated countries in EU, we argue that a key to accelerating development, absorption, and diffusion of new technologies is to support those activities in medium and large entities. Although in the more integrated EU countries the impact on innovation activity depends more on SME's, the new integrated countries should foster more on the medium and large firms in this transitional period and slowly (a very long term) make their efforts to the similarity for the policy of developed countries. Based on the empirical research of 5209 Polish enterprises, we model innovation activities concerning the firm size. The study includes a brief review of the Neo-Schumpeterian literature, followed by the description of study method. Next, we present results of the probit analysis. The paper ends with the conclusions, limitations, and main implications of this research including propositions of innovation policies interventions.*

**Keywords:** European Union, firm size, industry, innovation, integration

**JEL Classification:** L50, O30, O52, P23

### **1. Introduction**

In the past economists linked economic growth and innovation with monopoly and large companies. Schumpeter's (1942) first hypothesis assumes that economic growth takes place in the process of "creative destruction". Thus, the "traditional" industrial structures such as products, processes and organizations are constantly subjected to a confrontation with the 'new' innovation activities. This kind of "industrial change (...) is the basis of the functioning of the capitalist economy" (Schumpeter, 1942). This "creative destruction" is seen as the way of leading into higher profits and welfare. At the core of it lies risky innovation activity. The dynamics and systemic nature of innovation were introduced in the complex-system-oriented Neo-Schumpeterian evolutionary economics (Antonelli, 2011; Consoli Patrucco, 2011; Dopfer, 2011). According to this perspective, the innovation process at the enterprise level is considered as a set of activities related to each other through mutual feedback, while innovation is the result of an interactive learning process that often involves several actors from inside and outside the company (Lundvall, 1992). Innovation and its diffusion are thus the result of those collective interactions that evolve over time. They not only accelerate technological change, but give an opportunity for economic development in less developed countries. Our approach is focused on the determinants of the development and diffusion of innovation process and product (Edquist and McKelvey, 2000; Ranasinghe, 2017). Our concept of the

national innovation system assumes that it is a system of interrelated institutional and structural factors in the economy and society, manifested by three basic elements (industry, R&D and business institutions) and links between them. In such a system industry is defined as a set of entities operating in a given geographical territory. The actors of such a system can not only interact with each other but also with other institutions. Thus, both internal and external interactions are at the core of such a system. In Europe, the national innovation systems shape regional innovation systems' performance and form a functional network (Carrincazeaux & Gaschet, 2015). However, each country has a unique historical, geographical and cultural characteristics, different political and social systems, as well as economic and demographic features. Furthermore, innovation systems constantly evolve and therefore modern approach of the innovation process is referred to a dynamic interactive model of innovation (Freeman, 1987; Lundvall, 1992; Nelson, 1993). The impact of firm size on innovation activity has been discussed many times, but it is still ambiguous (Pérez-Cano, 2013; Gil, Figueiredo, 2013; Herrera, Sánchez-González, 2013). Moreover, this approach not only has evolved, but it has changed quite dramatically over time. At first, the ability to develop new technology was seen as the domain of large enterprises and imperfect competition (Schumpeter, 1934; Kamien, Schwartz, 1975). Drucker (2014) argued that small and medium enterprises are the most important innovators. The latest research suggest the importance of SMEs as sources of new-to-the-market innovation and the potential value of including such firms in future innovation studies (Dzikowski, 2018; Roper & Hewitt-Dundas, 2017). The impact of firm size on its innovation activity seems to be more heterogeneous in nature than previously assumed. It depends on many other factors (Audretsch, 1995, p. 175). The empirical analysis for 22 manufacturing sectors, broken down in three firm size classes, for eight European countries show that product and process innovations, though having some complementarities, are associated to different innovative inputs and strategies pursued by firms. Furthermore, the study confirms the differences in the determinants of product and process innovation, and the patterns emerging across firm size in European manufacturing industries (Vaona & Pianta, 2008). Much evidence exists in favor of the thesis of technological improvement in the economy by stimulating innovation in large entities. Such cases are common in economically underdeveloped countries, where entrepreneurship is not sufficiently well developed and widespread (Ács, Autio, & Szerb, 2014). In the "catching up" economies the industrial structure has a high share of low-tech entities which translates into a small share of high technology products in international trade. Based on the 10-years period of research on innovation of industrial enterprises in Poland, we assume that the improvement of the structure of international trade of domestic firms is based on the evolutionary changes in both the enterprise size classes as well as their technology (Świadek, 2007). New solutions are generally acquired by passive transfer of technology. The more the company takes part in the international industrial chain, the faster it adapts new technologies (Woodward, 2005). Furthermore, firm size has no effect on the types of implemented innovations. There are, however significant differences between the implementations and the initiation of these processes in firms in the world (Damanpour, 1992). It can therefore be concluded, that this polemic has not been completed, and the impact of firm size on the development of new technology seems to be a phenomenon much more diverse than previously thought. Studies conducted worldwide suggest higher public support for large companies due to higher probability of development for all market, whereas the same support used at SMEs level generates new solutions mainly at companies' level (Herrera, Sánchez-González, 2013; Pavione, Pezzetti, 2016). As argued Link (1980), large firms have an innovative advantage in markets with imperfect competition, but small firms are characterized by a higher predominance of innovation in markets similar to the model of perfect competition.

## 2. Problem Formulation and Methodology

The main hypothesis of the study is the assumption that innovative activity of enterprises, operating in the country aspiring to be called a developed economy, depends largely on their size. Furthermore, a better understanding of innovative processes and their limitations within the national innovation system may help to develop a unique set of diversified development paths that can accelerate and enable to manage the development, absorption and diffusion of new technology. The main objective of the study is to determine the impact of firm size on the innovation activity of the Polish industrial system. The secondary goal is to define boundary conditions for the model structure of national innovation networks that take into account the present level of development of Polish economy and allows to create a set of smart innovation policies. The survey conclusions represent only a part of results achieved during the research and further analysis. The study was based on a group of 5.209 industrial enterprises (the number of correctly completed and returned questionnaires), including 4615 enterprises with exclusive national capital, 281 with foreign capital and 313 companies with mixed ownership structure. The data cover a period of five years from 2008 to 2012. The database is constantly updated. Data were collected on the basis of a telephone interview and questionnaire. Only correctly completed questionnaires were qualified for next stages of analysis. Selection of the sample survey is approximately equal to the structure defined by the Central Statistical Office in Poland. Additionally, the survey includes firms employing less than 10 people. Thus, it is possible to map the functioning of national industrial system in Poland as a whole.

**Table 1. The Structure of Industrial Enterprises by Firm Size and Technology Level**

Firm size	Total [%]	Technology level	Total [%]
Micro (<10)	36.3	Low	52.2
Small (<50)	36.3	Medium low	29.6
Medium (<250)	21.5	Medium high	1.2
Large (>249)	5.9	High	5.0

Source: own research

The analyzes are static, which is important to maintain comparability of data and were conducted in a three-year arrangement in accordance with the standards of methodological innovation surveys carried out in OECD countries (OECD, 2005). In the case of a model where independent variable reaches a value of 0 or 1, the expected value of the dependent variable can be interpreted as the conditional probability of the event at fixed values of the independent variables (Berkson, 1944; Berkson, 1990; Aldrich, Nelson, 1984). Thus, we use a probit regression (Liao, 1994). The use of probit models helps to determine the probability of innovative behavior depending on the adopted boundary conditions. There are the following dependent variables: (a) expenditure on innovation activities in relation to their structure (research and development, investment in new machinery and equipment, investments in buildings, land and new computer software), (b) the implementation of new products and processes with detailed solutions in this area (new products, new processes), c) the innovative cooperation in terms of the subject (with suppliers, competitors, customers, universities, R&D labs, foreign research institutes). A set of independent variables reflects the innovation activity firm can adopt on the basis of the methodology used for the OECD countries (OECD, 2005). The statistical verification of models and their parameters were based on statistics Wald's Chi-square and associated test probability  $p$ , and Student's  $t$ -test. All calculations were performed by using Statistica software. Only models that meet the criteria for assessing the statistical significance parameters are presented with standard errors, statistics assessing the relevance

of the parameters and the probability of occurrence of phenomena. The positive sign in front of a parameter means that the probability of an innovative event is more likely in a given group of companies than the probability of it in other types of enterprises. There are seventy two logit models and the majority of them reached statistical significance.

### 3. Problem Solution

#### 3.1 Innovative Activity in Micro Enterprises Sector

In the group of micro enterprises logit models show uniform and interesting results. All logit models are statistically significant and have a negative parameter. This means that micro enterprises are statistically less likely to engage in any innovation activity than the other groups. These negative relations concern all three areas: financial investment in R & D, implementation of new processes and innovative cooperation. These results call into question the need to support that group through a variety of innovative policy instruments whether at national or regional level. Hence, the question arises whether Drucker assumption about the important role of micro enterprises in the generation and transfer of new knowledge in a country like Poland is correct.

**Table 2: The Parameter Value for the Independent Variable "Micro Enterprises" in the Probit Models Describing the System of Industrial Innovation in Poland**

Source: own research

Further analysis of the probabilities shows some other interesting regularities. First, there is wide variation between the values of the probabilities in the areas of financing, implementation

and innovation cooperation. Although micro enterprises are less than the other companies keen to finance and implement new solutions, they are much more interested in those aspects of innovation rather than entering into innovative cooperation. High probability values are for investments in fixed assets (0.66), including the purchase of technical equipment and machinery (0.59) and software (0.50), implementation of new products (0.48) and processes (0.61), with emphasis on new methods of production (0.40). In the area of innovative cooperation they are much more interested in the vertical linkages - with suppliers (0.22) and customers (0.17), while those of a horizontal nature occur very rarely, regardless of the kind of entity (probability close to zero). To sum up micro enterprises are significantly less likely to carry out various forms of innovative activity, mainly in the area of R & D, investments in new buildings, the implementation of new technological processes in non-production systems and innovative horizontal cooperation. Nevertheless, there are areas that could potentially be supported by different mechanisms of innovation policy. This applies to the purchase and implementation of new machinery and equipment, implementation of new products and production methods. Hence, we believe that this group of companies inhibits technological progress in the Polish economy, and thus at this stage of development they should not be supported by innovation policy instruments. However, support instruments should be used when companies take deliberate actions to create new technologies (positive parameters, but small probabilities).

### 3.2 Innovative Activity in Small Enterprises Sector

Small enterprises sector is the second largest group of companies in the study, but there is the smallest number of statistically significant models as well. This is not an unexpected phenomenon. Moreover, the estimated parameters in the two cases have the negative sign, while in two successive positive.

**Table 3: The Parameter Value for the Independent Variable "Small Enterprises" in the Probit Models Describing the System of Industrial Innovation in Poland**

Innovative feature	Parameter	Standard error	Student's t test	Chi2	P> z	p <sub>1</sub>	p <sub>2</sub>
R & D expenditure	-0.091	0.037	-2.45	6.02	0.01	0.34	0.37
Investment in new fixed assets	+0.136	0.040	3.41	11.72	0.00	0.78	0.74
Implementation of new technology processes	+0.138	0.039	3.54	12.56	0.00	0.76	0.71
Cooperation with foreign R&D units	-0.249	0.092	-2.71	7.80	0.01	0.01	0.02

Source: own study

There is a slight chance that small companies might carry out R&D activity or cooperate with foreign R&D units in comparing to other class sizes. In contrast there are great chances that they invest in new fixed assets and implement new technology processes. Thus, the sector of small-sized enterprises is concentrated on passive, but technologically advanced transfer of knowledge. It turns out that the small industrial enterprises in Poland do not have a pro-innovation approach, but at the same time they are not anti-innovation, as previously described micro-entities. Thus, one can say with a high probability that in the next few years, small businesses under the influence of appropriate support should become a pillar of innovation in Poland. It is also worth noting that the systemic use of national innovation policy instruments will contribute to the further deepening of structural differences in the Polish industry. One of the reasons is easier access to these resources in the most developed regions. In conclusion, small industrial enterprises in Poland are in a transitional phase between the lack of interest in

innovation activities and active involvement. These changes are evolutionary in nature, and therefore require time. The use of systemic mechanisms to stimulate this sector, however, will lead to increasing polarization between regional efforts in the area of innovative companies. It remains an open question whether the improvement in innovation performance of the economy should be guided by the desire to reduce the differences between the provinces, or perhaps we should focus on the strong acceleration of innovation processes where they have a high chance of occurrence.

### 3.3 Innovative Activity in Medium Enterprises Sector

In the group of medium-sized industrial enterprises seventeen statistically significant models were estimated. All models have positive function parameters what suggests that this sector is more innovative then other groups. This phenomenon is the systemic nature all over the country and it differs from what we observed in micro and small enterprises sectors.

**Table 4: The Parameter Value for the Independent Variable "Medium Enterprises" in the Probit Models Describing the System of Industrial Innovation in Poland**

Innovative feature	Parameter	Standard error	Student's t test	Chi2	P> z	p <sub>1</sub>	p <sub>2</sub>

b) Non production systems	+0.456	0.043	10.62	112.48	0.00	0.46	0.29
c) Support systems	+0.402	0.044	9.06	81.06	0.00	0.35	0.21
Cooperation with suppliers	+0.141	0.045	3.16	9.86	0.00	0.30	0.25
Cooperation with Polish Academy of Sciences units	+0.245	0.097	2.54	6.16	0.01	0.02	0.01
Cooperation with universitites	+0.354	0.067	5.27	26.69	0.00	0.07	0.04
Cooperation with domestic R&D units	+0.355	0.056	6.33	38.76	0.00	0.13	0.07
Cooperation with foreign R&D units	+0.416	0.086	4.86	22.43	0.00	0.04	0.01
Cooperation with customers	+0.151	0.046	3.26	10.50	0.00	0.25	0.20
Overall innovative cooperation	+0.264	0.042	6.23	38.84	0.00	0.51	0.41

Source: own research.

The detailed analysis of the calculated probabilities show some interesting regularities. Firstly, some of the innovative activities have high chances of occurrence, although there is also large internal differentiation. The probability of implementation of new technology processes is (0.84) whereas the probability of implementation of new production methods decreases to (0.55). The probability of implementation of nonproduction systems decreases to (0.46). Finally the probability of implementation of support systems amounts (0.35). This appears to be the example of typical substitution effect. Companies typically implement one of the three technologies, but they rarely implement all at once. It may be due to high capital requirements. Secondly, the high probability of funding and implementation of new products and processes are opposed to low chances of innovative collaboration. The probability of vertical innovative cooperation is much higher than the probability of horizontal one. Innovative cooperation is also subject to large internal variation, as indicated above for the implementation processes. The chance of overall innovative cooperation amounts to as much 51.0%, while the probability of innovation cooperation with suppliers is 30.0%. Medium-sized companies quite often take cooperation in vertical industrial chains what leads to the creation of new technological solutions. Finally, the probability values indicate which areas of innovation activity require special interest and support. At this point, we should pay special attention to the thresholds. This raises the question about the legitimacy of public support for innovative activities which probabilities are very close to the extreme values of 0 or 1. Low probability of innovative activity will remain low even after the application of broad public support. On the other hand, when the probability is high (greater than 0.70), innovation policy enters the areas in which the market is already fully operational. Perhaps it would be advisable to support those areas in which the probability of innovation is between (0.30) and (0.60). Then, there is a good chance to effectively stimulate those enterprises which are not as innovative as they would like and positively affect the whole industrial system. In the case of medium enterprises, those areas include: funding for research and development, investment in new buildings, the implementation of new products and processes (large internal differentiation in processes should be concerned), overall innovative cooperation (particularly with suppliers and customers). To sum up, medium enterprises are much more active in the area of innovation than micro and small companies, thus they are a main stimulator of innovation processes in the national industrial system. This impact is therefore systemic nature, which is particularly important when trying to program effective innovation policy instruments. The strength and scale of the impact of this sector on industry innovation can be described as substantial. At the same time there is a great diversity of activities what proves their substitutable character. This diversity creates the need for developing a system of support depending on the goals we intend to achieve in this group of enterprises both at national and regional levels.

### ***3.4 Innovative Activity in Large Enterprises Sector***

Large companies are the least-represented group of entities. There are 309 enterprises that participated in the survey. All probit models have proved to be statistically significant. What is more important all take a positive sign, which means that large firms, as previously described medium-sized enterprises have a positive impact on innovation processes. This effect is also a systemic nature.

**Table 5: The Parameter Value for the Independent Variable "Large Enterprises" in the Probit Models Describing the System of Industrial Innovation in Poland**

Innovative feature	Parameter	Standard error	Student's t test	Chi2	P> z	p <sub>1</sub>	p <sub>2</sub>
R &D expenditure	1.001	0.077	12.88	177.28	0.00	0.72	0.33
Investment in new fixed assets (including):	+0.411	0.091	4.53	22.01	0.00	0.86	0.75
a) buildings and grounds	+0.457	0.074	6.14	37.08	0.00	0.41	0.25
b) technical equipment and machinery	+0.363	0.082	4.43	20.47	0.00	0.79	0.67

Overall innovative cooperation	+0.550	0.075	7.36	55.30	0.00	0.63	0.42

Source: own research

By analyzing the probability levels we can notice that, in the areas of financing and implementation of new technologies, they range in values from (0.41) to (0.88). Hence, it means a very high chance of implementation of these activities. So, if probability of a given innovation activity is high should we support this kind of innovation activity? In other words, if innovation policy supports highly likely innovative activities, it will replace effective market mechanisms. On the contrary, large companies behave in the area of overall innovative cooperation. The chance of overall cooperation in the area of innovation is 63%. However, the structure of this cooperation seems to be diversified. It was found that the highest probability is for innovative cooperation with suppliers (0.38), customers (0.36) and domestic R&D units (0.20). The latest should become important areas of potential support, with good prospects for sparking innovative processes in Poland. In other cases, innovative cooperation opportunities are in the range of 4% -10% and again the question arises about the legitimacy of the system to stimulate innovation cooperation between companies that are generally not interested in it. This concerns mainly cooperation with competitors, cooperation with Polish Academy of Science units and cooperation with universities or foreign R&D units. Unfortunately most of those institutions play central roles in public support programs in Poland (those associated with cluster development and cooperation between science and business). This fact may explain why these institutions have so low impact on the growth of innovation in Poland. And this is due to the current level of development of the Polish economy, the low level of confidence in the market (high transaction costs) results in the low dynamism of innovative industrial system. In conclusion, large industrial enterprises in Poland positively and systematically support innovation processes in the economy, just as medium-sized companies, with the difference that the probabilities take much higher values. We express serious doubts about the legitimacy

of supporting large companies by public funds in the areas of R&D funds and implementation with some small exceptions. However it would be advisable to support innovation cooperation with both suppliers and customers and domestic R&D units. Perhaps such help may accelerate positive changes within the whole industrial system. It is worth mentioning that the conclusions reached on the basis of the study are very detailed and often different from national assumptions made for public innovation support programmes in Poland. It seems that public innovation support programmes do not take into account neither the nature of the Polish economy nor the level of development of the domestic industry, and are often adopted without reflection from countries with a much richer tradition in building a market economy. Thus, their performance is so poor and often raises controversy about the legitimacy of the acquired targets, directions and methods of implementation.

#### **4. Conclusion**

Firm size directly effects the innovative activity of Polish industrial enterprises and it indirectly affects the national innovation system in Poland. Furthermore, the activity of micro enterprises negatively supports innovation at the present stage of economic development of the industrial system in Poland. In the last 15 years a deep process of institutional reforms and economic reorganization took place in central and eastern EU countries (CEE) and these changes occurred in a context of general economic integration. This economic integration includes innovation facilitation. Nevertheless, developing national innovation policies should include national economic conditions. Hence, in the case of the limited availability of public funds to stimulate innovation activities, support should be directed to more promising sectors to achieve higher growth. Small enterprises, in turn, are in a transitional phase between the lack of interest in innovation activity and keeping it active. These changes are evolutionary in nature, and therefore require time. The use of systemic mechanisms to stimulate this sector, however, will lead to increasing polarization of regional innovation efforts. It is an open question whether the improvement in innovation performance should be guided by the desire to reduce disparities between regions, or perhaps we should focus on the strong acceleration of innovation processes where they have a high chance of occurrence. Medium sized enterprises are one of the two main promoters of innovation processes in the national industrial system. Their influence is systemic nature, what is particularly important when trying to program effective innovation policy instruments. Their power to influence and more importantly the potential scale of the impact on the entire industry can be described as significant. The high diversity of innovative activities rather proves their substitutability than complementarity. Hence, the need to develop a variety of support options, depending on the objectives. Impact of large enterprises is also systemic and positive, but it reaches higher values of probability. However, there are some doubt whether financing and implementation of innovation should be supported in large enterprises. On the contrary, we believe that supporting cooperation between large enterprises and national R&D units will help to increase industrial innovation within the national innovation system. It seems that currently implemented public support for innovation in Poland does not take into account the characteristics and level of development of the national industry. Thus, its performance is so poor and often raises controversy about the legitimacy of the acquired targets, guidelines and methods for their implementation. Economic literature does not clearly identify what type of firm size should be responsible for the processes of creating new technologies especially in countries, where so called "technological gap" is estimated for several decades. Although it is believed that the SME sector is mainly responsible for the dynamic process of diffusion of new developments in the local and regional market (endogenous growth theory) whereas their technological level is not important. However, we believe that these interactions often depend on the specifics of the

given industrial system and its present phase of its development. According to evolutionary perspective, with an increase in industrial capacity and improve its competitiveness, the responsibility for accelerating technological progress is moving from large to small firms. However, the owners of micro enterprises prefer no risky activities in Poland. It is recommended that national innovation policy should not only take into account the need for different pro-innovation mechanisms for different firm sizes, but it also should relate to different stages of maturity of the national industrial system to better support development, absorption and diffusion of new technology.

### **Abstract**

*The process of globalization of markets, connected among others with the integration of the European Economic Area (EEA), generates the need to adopt universal regulations that will ensure direct comparability of the information presented in the financial statements of enterprises operating in different countries of European Union. The aim of the article is to present the changes that have been introduced in the International Financial Reporting Standards (IFRS), which have entered into force in Poland since January 2018. The applied research methods involve a review of legal acts and literature on the subject as well as the use of data from reports on the implementation of IFRS in Poland. As a result of the analysis, it was observed that countries which, like Poland, belong to the EEA, implement changes and new IFRS to their law, which means that every year enterprises must adapt their reporting to new regulations. Based on the results of the analysis, the subjective scope of the obligatory and optional preparation of financial statements according to IFRS was presented in accordance with the applicable Polish law. Problems and benefits resulting from the implementation and application of new IFRSs were also presented.*

**Keywords:** *European integration, European Union, International Financial Reporting Standards*

**JEL Classification:** *M41, M40, M48*

### **1. Introduction**

Globalization has become the most important phenomenon of the global economy (Baláž, 2014), and accounting is a scientific field strongly influenced by the European integration process. The economic processes within the European Union (EU) forced the need for standardization in the area of financial audit. Such action is aimed at unifying the interpretation of reporting documents. The principles applied in this field should help in preparation of reports created by capital groups, increase comparability of information contained in those reports, and in the process, lead to an unambiguous interpretation of data as well as their reliability and credibility. The uniformization of EU law in the area of accounting was the directive in this area. The legal nature of EU law allowed to choose the methods and means of their implementation in connection with local traditions and practices (Świetla, 2008).

In the present article, we will discuss the problems concerning unification of accounting solutions within the framework of European integration and in relation to the systems of countries outside the European Union.

## **2. Problem Formulation and Methodology**

An important part in the European integration process is formed by the harmonization and standardization of accounting and financial reporting, which is aimed at ensuring transparency and comparability of financial statements of economic units originating from countries with different legal systems, socio-economic determinants, and cultural traditions. The transparency and comparability of financial reports, which are used by various groups of stakeholders, should be ensured by the International Financial Reporting Standards (IFRS) established by the International Accounting Standards Board (IASB), a major institution in the area of worldwide unification of accounting. The EU member states, including Poland, are required to apply EU directives, five of which relate to accounting. Subsequent changes and new IFRS are incorporated into the community law in the form of regulations of the European Commission and are implemented to the national law of EU members. In Poland, listed companies and financial institutions are obliged to apply IFRS. This obligation and acceleration of work on standards took place in connection with the financial crisis and collapse of large enterprises in recent years. Changes in IFRS mean that every year enterprises must adapt their reporting to new regulations.

The aim of the article is to present the changes that have been introduced in the IFRS, and have come into force in Poland since January 2018. To achieve this objective, legal acts and literature on the subject were reviewed as well as data from reports on the implementation of IFRS in Poland was used.

## **3. Premises for Applying Unified Accounting Principles as Part of the European integration**

The concept of integration is used on the basis of various sciences and areas of life. It means fusing, merging, making a whole from parts. Integration processes are one of the most characteristic phenomena occurring in contemporary Europe. European integration is a form of international and regional integration, a process that occurs on economic and political planes (Kalinowska, 2015). In order to remove regional economic disparities, the EU realizes a cohesion policy. Such policy is justified economically and socially. The structural funds contribute to the increase of GDP per capita as well as to the reduction of unemployment, as described by Dorożyński in his studies in paper on effectiveness of the EU cohesion policy and its impact on the development of regions (Dorożynski, 2012).

In the light of European integration, diversification plays an important role in accounting. This variety may be seen in the way the financial information is presented, as well as the way in which this information is interpreted by both internal and external recipients. The main purpose of standardization processes has become the normalization of the accounting field in the European Union countries, and the unification of principles of the area in the world (Krasodomska, 2008). Undoubtedly, the strongest effects of globalization can be seen in the financial system (Dvoroková, 2014), in which there are many factors affecting the accounting system. The globalization of the economy and the integration of financial markets combined with their liberalization have influenced the development of financial markets. Processes indicated in this study affect the functioning of the financial system positively, leading to increase in the efficiency of institutions and financial markets. Globalization means that interdependent functioning global economy raises world-wide problems. Financial crises they do not touch individual economies, but they have an international dimension (Domańska - Szaruga, 2009).

C. Nobes and R. Parker point out seven elements involved in discrepancies in accounting and financial reports. They are the following: legal systems, sources of financing business operations, tax systems, the accounting profession, inflation, accounting theory, and historical events (Nobes, Parker, 2000). In discussing the impact on the accounting, S. Lawrence points to four leading factors, which are the following: cultural, political, legal and economic (Lawrence, 1996) causes. The specificity of each country's accounting system originates from the law of the state in which the system is applied. This means that accounting becomes an obstacle to decisions being taken by the global market participants. Figure 1 shows the impact of the applied solutions on the unification of the Polish Accounting Act.

#### 4. Amendments to IFRS Introduced in 2018 in Poland

The purpose of the International Financial Reporting Standard 15 Revenue from contracts with customers, is to establish the principles according to which an entity provides users with financial reports containing useful information pertaining to the nature, amount, time and uncertainty of revenues and cash flows arising from contracts with customers.

In accordance with the standard, revenues are recognized in such a way as to reflect the transfer of promised goods or services to the client in an amount that presents the remuneration to which they will be entitled in exchange for those goods or services. By applying this standard, the entity takes into account the terms of the contract and all relevant facts and circumstances. It also includes all practical solutions pertaining to contracts of similar characteristics and made in similar circumstances (Commission Regulation (EU) 2016/1905 of 22 September 2016 ).

According to the new standard, for many entities that sell various services and goods under a single contract with the client, the transfer of goods and services will take place in different reporting periods. Currently, the recognition of revenue included mostly values specified in the contract. After January 1, 2018, revenue will be recognized in relation to the prices of goods and services that the entity would use in a regular sale transaction. This means that some revenues will be recognized for tax purposes (those will be based on the values specified in the contract), and other for accounting purposes (The Legal newspaper, 2018). In accordance with the standard, a change in the value of recognized revenues may occur for many companies. It includes entities that sell different services and goods under one contract with the customer.

Published in 2014 and introduced 4 years later, amendments to the International Financial Reporting Standard no. 9 (entitled Financial Instruments) were to improve financial reporting on financial instruments, with relation to the problems that emerged in this area during the financial crisis (Commission Regulation (EU) 2016/2067 of 22 November 2016 ).

The purpose of the standard is to amend financial reporting principles for financial assets and financial liabilities. Such principles would be useful to provide information for users of such reports who could assess the amount, timing, and uncertainty of future cash flows of a given entity (Commission Regulation (EU) 2016/2067 of 22 November 2016 ). The draft of IFRS 9 has been implemented since 2008 and was to replace the International Accounting Standard 39. The implementation was carried out in stages. New requirements for classification and valuation were published in 2009. Next year, new requirements related to financial liabilities and removal of items from the balance sheet were added. And in 2013, changes regarding the general model of hedge accounting (Deloitte, 2016) were issued.

Significant changes to the standard are introduced in the following areas:

- classification and valuation of financial assets and liabilities;
- impairment of financial instruments;
- hedge accounting;
- impact of own credit risk on the valuation of financial liabilities.

The largest impact of IFRS 9 will affect financial institutions, especially the credit loss model. The standard introduces a new model of impairment loss recognition - the expected credit losses (ECL) model. Until now, the impairment loss was recognized only when there was objective evidence such as financial difficulties or failure to meet the terms of the agreement by the debtor. Under the new rules, as early as the initial recognition of financial assets in the balance sheet, enterprises will have to estimate the expected credit losses using a three-step model based on changes in credit risk (PwC, 2017).

The current model of the division of assets has been replaced by a classification referring to the business model used by the enterprise, and to the nature of the flow from the instruments. The consequence is the adoption of an appropriate valuation method, e.g. an amortized cost valuation or value measurement (Pielichaty, 2016).

IFRS 9 introduces a highly modified model of hedge accounting, including the extended obligation to disclose information on risk management. It is a fundamental reorganization of hedge accounting since it combines accounting principles and risk management, allowing for better presentation of these activities in financial statements (Mazurowska, 2015).

## **5. Problems Related to the Introduction of IFRS in Poland**

The goal of unifying accounting regulations on an international scale is:

- minimizing the ways of presenting business results by enterprises operating in different markets;
- increasing the comparability of financial statements of enterprises from different countries (Dratwińska - Kania, 2011).

Poland's accession to the EU imposed the obligation to adopt national accounting and financial reporting solutions to EU standards. The possibility of raising capital for Polish companies was connected with the need to apply IAS and IFRS from January 1, 2005. For listed companies and domestic recipients of information accustomed to reports prepared pursuant to the Accounting Act, these changes have become a serious impediment, because it is they who have to present and interpret data included in financial statements (Wasilewski, Rusinkiewicz, 2008).

In Poland, regulations regarding financial reporting, relating to aspirations for European integration, oblige some entities (i.e. those listed in the public sector) to apply IFRS. Other companies defined in the EU directive on financial reporting may report in a greatly simplified

way. This leads to a serious difference in terms of transparency and comparability of information provided to those interested in financial statements of reporting units and their financial activities (Ignatowski, 2016).

Amendments and new IFRS are incorporated into EU law in the form of implementing regulations of the European Commission. Issues related to international standards in the European Union are regulated by Commission Regulation (EC) No 1126/2008 adopting 29 IAS and 8 IFRS. By the end of 2013, there were 39 more Commission regulations amending Regulation No. 1126/2008 (Frymus, 2014).

**Table 1: Approved and Implemented Changes to IFRS and IAS in 2015-2018**

Name of the standard	Year of introduction
IFRIC 21 Public Fees	2015
IFRS 1 Application of IFRS for the first time	2015
IFRS 3 Business Combination	2015
IFRS 13 Fair Value Measurement	2015

Amendments to IAS 12 Recognition of Deferred Income Tax Assets Resulting from Unsettled Tax Losses	2017
Amendments to IAS 7 Disclosure Initiative	2017
IFRS 9 Financial Instruments	2018
IFRS 15 Revenue from Contracts with Customers	2018

Source: Own elaboration

Table 1 presents the changes and new IFRS that were approved and introduced in Poland from 2015 to 2018. As we can see, there are regular changes to IFRS every year. Existing standards are being supplemented and clarified, new ones are also published, including previously unidentified issues and new challenges to financial reporting. Preparing financial statements in accordance with IFRS is compulsory for companies listed on stock exchanges, for the

banking sector, and entities whose parent companies prepare financial statements in accordance with IFRS. These entities are grappling with new changes every year, which generates additional costs, and requires changes in IT systems or internal policies, which in turn involves time and preparation. Monitoring the changes which take place in MSSF is not easy due to a number of implemented modifications in the current regulations, but also announcing new standards. It is important to prepare oneself for applying new regulations and effective use of time between the moment of the publication of a new standard and the date it is used, both at the national level and at the enterprise level. An example is a situation which was present in Poland in 2015 when the International Financial Reporting Interpretations Committee's (IFRIC) Interpretation entered into force and was related to taxes and charges. Many banks and supervisory authorities were discussing how to adjust the content of the Interpretation to the Bank Guarantee Fund charges applicable in our country (PwC, 2017). It caused uncertainty and, in some cases, changes in financial data. It is important to monitor the publications of regulations on an ongoing basis and analyse their influence on accounting and reporting of units. Amendments made very often influence on not only accounting processes, but also on operational actions, thus it is significant to introduce the policy of implementation of amendments made by the standards.

## **6. Conclusion**

Globalization processes in the world economy as well as the integration of the states forming the European Union have forced the need for standardization and harmonization of accounting and reporting in enterprises, and the adoption of uniform regulations by all member states. The advantage of adopting common rules is the opportunity to present a reliable and clear picture of the company, which increases the reliability of reports, and makes it easier for investors to invest effectively. The financial reports of entities applying IFRS are comparable to the reports of other companies, including foreign companies, which facilitates raising capital on foreign stock exchanges, and increases investment efficiency, reducing the costs associated with preparing reports according to a uniform convention.

The implementation of IFRS is also associated with some inconveniences. The transition to IFRS is a complex, very time-consuming and expensive process. The main problems concern the following:

- companies not subjected to obligatory control are not able to use many simplifications allowed by the Accounting Act, and not provided by regulations included in IFRS;
- some entities cannot apply national regulations regarding financial instruments;
- there is the need to specify and keep books in a functional currency other than zloty;
- there are difficulties in determining the correct value of fixed assets.

Other problems include deficiencies in the knowledge of accountants in the scope of applying IFRS. Additionally, entities applying IFRS are subject to the mandatory control of the statements. Another problem is the specificity of the Polish economy not regulated in IFRS, e.g. the right of perpetual usufruct of land, social facilities, low-value assets.

Over the years, the introduction of IFRS has been modified many times, and according to the authors, it can be assumed that this process has not yet been completed as evidenced by the fact that the work on IFRS and IAS is ongoing, and the IASB has approved IFRS 16 Leasing to be used after January 1, 2019. The financial situation of enterprises is crucial for the financial stability of world economy. A new model of financial assets' impairment should improve quality of financial statements in terms of the prediction of possible future losses.

## **Abstract**

*Tourism is an area of the economy which importance has been growing for many years. Its development depends on civilization changes, economic growth and improvement of social conditions of societies. The aim of the article was to show the relationship between economic growth and expenditure on tourism in the European Union countries. The European Union as a unified organism on the one hand, and on the other hand a conglomerate of states with different levels of economic development seems to be a good object of research. Data from Eurostat and national data sources for 2000-2016 were used in the analyzes. The research used tools in the field of multidimensional statistical analysis. The results obtained indicate an increase in spending on tourist services, accompanied by an increased demand. The closer analysis indicates a decrease in average spending on trips abroad in many countries with different levels of development.*

**Keywords:** *economic development, European Union, expenditure on tourism, statistical analysis*

**JEL Classification:** *F63, Z13, Z32*

## **1. Introduction**

The importance of services in the economy is visible primarily in highly developed societies (Kiryłuk, 2014). I am talking here, of course, about the implemented internal demand for tourist services (Cole, 2001). Share of this type of services is conditioned on the appearance of two factors at the appropriate level. The first are financial resources - actually their excess, which can be used to meet the needs which are less important than the basic ones. The second condition is to have enough free time, which can be spent on the use of tourist services (Batyk, 2010). In addition, an appropriate surplus of funds leads to the implementation of tourist services abroad. Here, however, the benefits for the economy can appear on the side of real service providers (in the place of their implementation) and intermediaries. Quite often, tourist destinations involve poor, usually politically stable countries. The existing opportunities are often used by tourism organizers from richer countries with large financial resources necessary for the full implementation of the service. The benefits are, of course, mutual, both for the local economy (entities) and organizers (entities) from developed economies. Also in this case, through the tax system, the benefits for entities operating on the international arena go to the resident (sending) countries. Apart from the non-economic (cultural, historical, social) factors, changes in the demand for tourist services due to changes in economic factors should not only be perceptible, but in countries with similar characteristics should also go in a similar direction. In this respect, the study of these dependencies, i.e. the (economic) wealth measured with GDP

per capita and the demand for tourist services for the European Union countries seem to be justified (Tugcu, 2014).

## 2. The Specifics of the Tourist Services Market

In contrast to other types of services, the implementation of tourism services depends to a large extent on the geographical and natural conditions of the site. Development of tourism depends on factors that we can influence, like:

- quality of offered services,
- quality of infrastructure used in the process of providing services (Piechnik, 2012),
- price attractiveness of the services offered (Kot at al., 2012);

factors that we are able to predict relatively well, diagnose like:

- affluence of potential customers / consumers (Seetanah, 2011),
- customers' expectations regarding the offer,
- assessment (subjective) of the attractiveness of the place of service provision and its form;

and highly unpredictable factors like:

- subjective assessment of tourist values and quality of services,
- fashion,
- weather conditions (Cannas, 2012),
- political situation (Secăreanu at al., 2012).

The last of these factors plays a significant role primarily in politically unstable countries such as North African countries, however, the collapse of the market in this region in recent years has resulted in increased demand for services in Europe and the accompanying increase in prices and the emergence of new destinations and new market participants. In the presented study, however, we take into account the demand for tourist services treated as internal or external - with the exception of a precise European or non-European destination. The study uses the Charvat index, calculated as the number of nights in relation to the number of residents, and other based on the expenditure on tourist services and the number of trips.

As a basis, it was decided to compare changes in expenditures on tourist services in the years 2007-2016 in the European Union countries. For comparison, the data was presented in Euro according to the purchasing power parity in constant prices from 2010. We have data on both domestic and foreign trips and accommodation (Crouch, 1994). The latter seems to be more reliable, since the number of trips does not directly reflect the time spent abroad, which is associated with majority of costs (Bobáková, Chylková, 2016). The values of expenses for accommodation (total expenses by the number of overnight stays) were then compared with household expenditures.

## 3. Household Expenditure and Expenditure on Tourist Services

Assuming that expenditure on tourist services is a derivative of the wealth of the society, it seems reasonable to examine the relationship between household expenditure and expenditure on tourist services.

Out of 27 countries surveyed (there are significant data gaps for Luxembourg) there is a negative linear correlation between household expenditures and expenses for domestic trips in 10 cases. Only for Bulgaria the correlation was positive and statistically significant ( $r_{xy} = 0.722$ ;  $p = 0.028$ ). However, if we look at spending on accommodation, it will turn out that along with the increase in household expenses, the average spending on domestic

accommodation also increases more often. Positive and statistically significant correlation was observed for 11 cases and negative only for Sweden ( $r_{xy} = 0.790$ ;  $p = 0.020$ ) and Croatia ( $r_{xy} = -0.653$ ;  $p = 0.041$ ).

\*significance at the level  $\alpha = 0.05$

Source: own elaboration on the basis of Eurostat data

In the case of expenses for trips abroad, it is not so clear. Exactly 5 out of 10 statistically significant correlations between the number of trips and household expenses turned out to be

positive. In the case of correlation with spending on accommodation, the situation is clear - all (10) statistically significant correlations indicated an increase in spending on foreign accommodation along with an increase in household expenses.

Obtained results are burdened with a certain error. It results from the fact of co-existence of all participants on the market (European / global) and formally their competitive "struggle". In connection with this, and in connection with changes in consumption in the European Union, the adjusted data on consumer expenditures was also used in analysis. To this end, average consumption expenditures was calculated for each year and then the amount of these expenses for each country were compared to the average. The resulting ratio was multiplied by spending and for each year, the amount of expenditure adjusted by the actual competition on the market of goods and services have been obtained. The expenses for accommodation were then referred to this value.

**Table 2: Results of the  $\beta$ -Convergence Study for Variables Determining the Demand for Tourist Services in European Union Countries in 2007-2016**

expenditure variable	Domestic			Outbound		
	$\Theta$	$\beta$	p	$\theta$	$\beta$	p
Trips per capita	-3.264	0.018*	0.003	-0.782	0.003	0.442

Night per capita	0.719	-0.003	0.478	-1.311	0.005	0.201
Expenditure per night	-1.383	0.018	0.178	-3.775	0.060*	0.001
Expenditure per trips	1.319	-0.006	0.199	-1.378	0.007	0.180

\*significance at the level  $\alpha = 0.05$

Source: own elaboration on the basis of Eurostat data

Assuming similar trends in the European Union, we should observe convergence in the scope of the studied phenomenon. If we look at the variables describing changes in the tourism services market, they should identify this phenomenon.

It turns out that statistically significant convergence is observed ( $\beta = 0.036$ ;  $p < 0.001$ ) in the case of expenditure per person on domestic tourism. Domestic demand in the EU countries is very similar and we can observe a kind of unification of its level at a rate of 3.6% per year. We cannot say the same about external demand ( $\beta = 0.004$ ;  $p = 0.659$ ). In this case, the only convergence concerns expenses per accommodation ( $\beta = 0.060$ ;  $p = 0.001$ ). This shows a relatively similar level of unit demand for tourist services (accommodation) in European countries. Here, the rate of reaching the hypothetical level of equilibrium is quite high and amounts to 6%. In terms of convergence, we also observe it for domestic trips per person ( $\beta = 0.018$ ;  $p = 0.003$ ). The frequency of trips per year, turns out to be more and more similar in the European Union, which is obviously an important information for market organizers.

#### 4. "Old" and "New" Union - a Comparative Analysis of the Demand for Tourist Services

It should be remembered that the European Union is not a monolith. We often find analyzes taking into account old EU members (15) - although due to the situation in some countries

(Spain or Greece) this is not always accurate - and new member countries (13) separately. In the case of presented analyzes, it also seems to be accurate.

**Table 3: Test Values for Two Averages for “New” and “Old” Union Members, Broken Down into Domestic and Outbound Nights, Trips and Expenditure (Per Capita)**

\*significance at the level  $\alpha = 0.05$

Source: own elaboration on the basis of Eurostat data

The study covered average expenses in the countries of both groups, classified by domestic and foreign, and the frequency of accommodation and trips within the same classification. The years 2007-2016 were taken into account. It turns out that in the case of foreign trips, these differences are almost every time (except for 2009 - probably the effect of the crisis) irrelevantly different from each other. Differences, on the other hand, concern domestic trips in almost all periods (except for frequencies in 2007). In the countries of the old Union, spending for domestic tourism is almost 2.5 times higher than for the new 13 countries. The lack of differences in foreign spending is largely due to the globalization of the tourist services market and the need to adapt it to all customers on the one hand and keeping prices adequate to some costs on the other. In the case of internal market in each country, it is shaped according to separate conditions. Thus, differences in expenses - are adequate to the prices of services, but probably also to conditions. It should be remembered that an objective analysis indicates a significantly higher benefits on the part of the tourist services sector in the case of countries with higher per capita spending on these services. Even with proportional profits (which seems to be natural), revenues at higher turnover also increase. Expenditures on foreign tourist services in the new 13 countries is significantly higher than expenditures for domestic services

in all periods, while in the case of old 15 countries these differences are statistically insignificant. In proportional terms in the old 15 countries, on average foreign tourism per person is up to 90% more than on domestic trips, while in the old 13 countries even more than 200% and not less than over 114%.

The structure of expenses for domestic / foreign trips depends on the size of countries. The larger ones spend more on domestic trips. Smaller for foreign ones, as their demand for tourist services is usually greater than possibilities in both quantitative and subjectively qualitative way. This applies both to the EU countries in general terms and divided into two groups previously indicated. Changes in the structure in general are slight, but visible for individual countries. The largest of them is a 31% decrease in the share of domestic expenditure for Hungary and 28% for Poland and a 78% increase in internal expenditure on tourism in Denmark, 49% for Sweden and 38% for the Czech Republic.

Source: own elaboration on the basis of Eurostat data

It should also be mentioned that the distribution of tourists in the area of individual countries is not uniform and is also subjected to changes not always of a similar nature. Data presented in Table no. 1 indicate that in the years 2002-2015 the number of tourists decreased in 41 analyzed regions, including two in a significant way. These were the regions of Inner London and Cornwall and Isles of Scilly belonging to Great Britain. The decrease in the number of tourists affected the most regions in Italy (9) and the United Kingdom (9). In turn, the fastest growth - over 10% per annum - was recorded by two regions: Yugoiztochen (12.1%) and Lithuania (12.7%). Dynamic or very dynamic increases concerned 26 regions.

Situation in Polish regions looks definitely unfavorable in comparison with the rest of Europe. With regard to the Schneider index (number of tourists in relation to the number of inhabitants), 5 Polish regions from Poland (Lubelskie, Opolskie, Podkarpackie, Śląskie and Świętokrzyskie) are in the last ten regions of the Union. The number of guests is, however, not entirely legitimate to use, much more accurate seems to be the number of nights - Charvat's rate - but also in this case in the last tenth there are 5 Polish regions (Lodz, Lublin, Opolskie, Podlasie, Greater Poland). The situation is probably a result of low level of infrastructure development. Density indicator of the accommodation base indicates that half of weakest ten in the Union are Polish regions - Lodz, Lublin, Masovia, Opolskie and Silesia. Only Pomorskie, Zachodniopomorskie and Małopolskie rank in those lists in the middle or upper part of the ranking. Each tourist is, however, a client and every day of stay (overnight) is a measurable inflow of financial resources. Every foreign tourist without accommodation (de facto visitors) is a daily income of PLN 362, while the accommodation increases this income to PLN 916. It is not difficult to notice that the benefits of greater involvement in the service of tourist traffic allow to generate quite large revenues, some of which may be reinvested to increase competitiveness. The effect of this is clear.

Observed relation between the amount of expenditures in nominal terms and the size of the country seems to be a natural phenomenon - especially with a relatively balanced population - however connection with the amount of expenditure per capita - not necessarily. The study confirmed statistically significant positive linear correlations for the size of countries and the volume of national expenditures per capita in general and in the old 15 countries. This proves that in these countries all actions supporting domestic tourism lead to increased profits from this activity due to internal demand. As for the "new 13", there was a statistically significant negative correlation between the size of the country and expenditure per capita for foreign holidays. Thus, in this case, the size of the country, provides some potential alternative in the scope of offered tourist services, and thus hampers expenditure on trips abroad.

Theoretically, it might seem that the changes (increase) in tourism services 'expenditure are mainly determined by the increase in individual countries' affluence (Antonakakis at al., 2015; Kyjonková, 2014). However, the results of the regression equation survey - for particular countries - illustrating the amount of spending on domestic and foreign tourist services, show dependence on gross domestic product.

## 5. Conclusion

Presented research indicates clearly a permanent increase on the side of tourist traffic measured both by the number of overnight stays and trips. This increase is not equal within the European Union and in many cases we see differences between the so-called Old Union "15" and later adopted states of the new "13". It was also confirmed - in line with assumptions - that larger countries spend more on domestic trips. Expenditures on foreign tourist services are similar, however, in the case of domestic expenditure in 2007-2016, countries of the old Union spent 2.5 times more than countries of the new Union. Despite this, spending on foreign tourist

services is clearly higher in both groups than for domestic services. The increase in internal demand results in the automatic improvement of the entire balance in this respect and returns to the budget in the form of investments and taxes (Schubert, 2011). Observed directions of changes as well as the structure of expenditures indicate development of the analyzed sector. Dependence of growing demand on wealth is evident - not in all cases - however, it is not the only, though often probably the main, determinant of increase in demand for tourist services.

### **Abstract**

*Relative to other European Union Member States, Poland's and the Czech Republic's performance across different well-being dimensions is mixed. Nevertheless, Poland and the Czech Republic highly improved their well-being outcomes after the accession to EU. When assessing the achieved level of human well-being, both material living conditions and quality of life have to be taken into account. The aim of this paper is to evaluate current state and progress in human well-being in two EU member states – Poland and the Czech Republic – with the use of comparative analysis. Attention is paid to conventional economic indicators measuring material living conditions, GDP per capita, disposable income and to indicators assessing the immaterial dimensions of citizens' quality of life. Moreover income distribution within societies and income inequalities are described as an essential part of measuring people's material well-being.*

**Keywords:** Czech Republic, European Union, income inequality, Poland, quality of life, well-being

**JEL Classification:** I31, I32, O15

### **1. Introduction**

English Oxford Living Dictionary understands under the term well-being *the state of being comfortable, healthy or happy* and considers terms *welfare, health, good health, happiness, comfort, security, safety, protection, prosperity, profit, good, success, fortune, good fortune, advantage, interest, prosperousness, successfulness* as its synonyms. Human well-being consists not only of individual well-being, but also of the social one. Therefore, well-being is attractive concept for scientists across wide range of social sciences – from psychology to economics. European Union Member States belong to economically developed countries with high quality of life and sustained progress in human well-being. However, existing disparities in well-being are evident in everyday life of individuals.

Poland and the Czech Republic joined with other eight states the European Union (EU) in 2004. Both countries were former socialist countries for which accession to the EU was a very important step in the process of economic transition. The Czech Republic and Poland are Central European countries as well as Slovakia, Hungary, Slovenia. Living conditions in the old EU Member States (EU15) are on average higher than in the EU Member States accessing

since 2004 (EU13). Presence of social and economic disparities at national as well as international level affect significantly fulfilment of the Europe 2020 Strategy and trajectory towards balanced and harmonious development (Poledníková, 2014). Despite existing large diversity in inequality patterns in EU Member States - revealing increases and decreases in inequality at the EU level (Stanickova, 2017) - EU membership is widely considered as the engine for socio-economic progress, and thus progress in individual and social well-being.

## 2. Problem Formulation and Methodology

In literature, well-being is defined in its multidimensionality covering key dimensions of material living conditions and immaterial quality of life. The most popular measures assessing inter-states differences in human well-being are Human Development Index and Happy Planet Index (Czech, 2016). The former one is commonly used especially when the progress in human well-being in developing countries is analysed because it covers only three essential dimensions of well-being: incomes, education and health status of the population. Therefore, it does not proof tiny nuances existing within these dimensions in developed countries. The latter measure contains shortcomings coming from the composite indicators used for its calculation (e.g. Ecological Footprint).

Report of Stiglitz, Sen and Fitoussi (2010) pointed out for the first time that if the well-being is assessed than its eight dimensions have to be taken simultaneously into account. These are material living standard, health, education, personal activities including work, political voice and government, social connections and relationship, environmental conditions, economic and physical insecurity. Since then, many researchers have paid attention to the formulation of composite indicators summarizing various aspects of individual and social well-being. Based on this report, OECD launched Better Life Initiative in 2011, introducing the Better Life Index, a composite measure evaluating eleven dimensions of well-being: housing, income, jobs, community, education, environment, government, health, life satisfaction, safety and work life balance (OECD [online], 2017). Chaaban, Irani and Houry (2016) developed the Composite Global Well-Being Index, spanning again several well-being dimensions, including: safety and security, health, education, housing, environment and living space, employment, income, life satisfaction, community and social life, and civic engagement. Recent researches focusing on well-being take into account its sustainability, for instance Mauro, Biggeri, Maggino (2018) presented a new approach of multidimensional measuring of well-being with the in-depth analysis of substitutability between different dimensions of well-being measures.

In this paper, our main objective is to evaluate current state and progress in human well-being in two EU Member States – Poland and the Czech Republic – with the use of comparative analysis. We focus on the period after the accession to the European Union to show the impact of European integration on well-being changes in these two countries. We plan to conduct the analysis of well-being in the period of the 1990s in our next paper and then to compare these results. The years covered typically range from 2004-2016 whenever possible. The question we ask here is precisely to what extent the Czech Republic (CZ) and Poland (PL) differ according to the level of income inequality and according to their achievements in selected dimensions of immaterial quality of life. We describe differences between PL and CZ, then we compare both countries with average European Union (EU28) achievements.

Based on current stage of research, we also apply multidimensional approach to the measurement, but we have no ambition to introduce our own composite measure in this paper. In contrast to this, we want to emphasize existing differences between the Czech Republic and Poland in comparison to European Union average. In our paper, we provide a comparison across a wide variety of well-being domains covering both material and quality of life

outcomes. Because of the limited size of the paper, we pay attention only to four dimensions of material well-being (GDP per capita, median equivalised disposable household income, housing conditions and income inequalities and poverty) and four immaterial dimensions of well-being (education, health, environmental conditions and personal security). We base our analysis on official statistical data reported by Eurostat, as well as on cross-sectional data collected at personal level within the framework of European Union – Statistics on Incomes and Living Conditions (EU-SILC) surveys, reporting self-evaluation of individuals' well-being.

### 3. Material Well-Being in Poland and the Czech Republic

#### 3.1. Incomes

Material well-being includes many dimensions like incomes and wealth. It is usually measured with GDP per capita and median equivalised disposable household income (Eurostat, 2013). Material living conditions also covers housing situation as well as income inequalities between people. All these measures are complementary to measure material well-being, because it is broader concept than only measuring economic production per capita (European Commission, 2009). According to EU and OECD suggestions to measure material well-being multilaterally, both GDP per capita and median equivalised disposable household income are analyzed in the paper (Eurostat, 2012).

**Figure 1: Gross Domestic Product at Market Prices, PPS per Capita in PL, CZ and EU-28 (average)**

Source: own calculations on Eurostat

However GDP per capita alone is not enough to inform about people's well-being (Stiglitz, Sen, Fitoussi, 2010), it is traditionally used in official statistics to describe people's possibility to fulfil material needs (buy and use goods). GDP per capita increased in the period 2004-2016 in Poland, Czech Republic and the European Union average. The highest GDP per capita growth rate was in Poland (76%). It was more than two times higher in Poland than in European Union average (30%) and a half times higher than in Czech Republic (45%). Moreover GDP per capita did not decrease in Poland during the crisis. At the moment of joining the EU the GDP per capita in Poland was 50% of the EU average (one of the lowest among new member states), the same relation in Czech Republic was 78% (one of the highest among new member states). Twelve years after accession to European Union GDP per capita (as a % of EU average GDP per capita) was 87% in Czech Republic and 68% in Poland. The level of GDP per capita in Czech Republic in comparison to Poland was 1,5 higher in 2004 and 1,3 times higher in 2016. As a result the economic gap between these two countries is smaller as well as the gap between Poland, Czech Republic and EU on average.

### 3.2. Median Equivalised Net Income

Median equivalised disposable household income, which can be considered as the income available to the household for spending or saving, should be compared with country GDP measures when evaluating material well-being. Equivalised disposable income is an indicator of the economic resources available to a standardized household (adjusted for household size and composition so that the incomes of all households can be looked at on a comparable basis) (Eurostat, 2014).

**Figure 2: Median Equivalised Net Income in PL, CZ and EU-28 average (in EUR)**

Source: own calculations on Eurostat

Relative to European Union average Poland’s and Czech Republic’s performance across the field of equivalised net income immediately after joining the EU was relatively poor. Although Poland is still among the countries with the lowest median income in EU, the highest rates of growth could be observed in this country in the period between 2005-2016 (PL 8,5%, CZ 6%, EU 2,5%). It should be noticed that as a result the gap between Poland, Czech Republic and EU average decreased. On the other hand the distance between analysed countries and EU average is much higher than when only GDP per capita is considered. Median income was only 20% of EU average in Poland and 33% in Czech Republic in 2004 and 35% of EU average in Poland and 47% in Czech Republic in 2016. The difference in these two dimensions is very significant and proves the necessity of measuring material well-being from different angles.

**Figure 3: Percentage of the Population in Poland, Czech Republic and EU-28 in 2013 Rating Their Satisfaction as High Medium or Low**

Source: own calculations on Eurostat

Material living conditions are important determinants of well-being in that they affect individuals and households choices and everyday lives. Although the objective living conditions are strongly related to the subjective assessment of the financial situation, the results of the EU study for Poland show higher level of satisfaction than could be expected given its objective living conditions. There is relatively high share of the population in Poland rating their material satisfaction high, but there is also much higher share of the population than in Czech Republic or EU rating their material satisfaction low (Fig.3). Moreover, the subjective assessments of the financial situation seem to be comparable between Poland and Czech Republic despite their relatively high gap in objective material well-being.

### 3.3. Housing Conditions

Housing is a major component of household's budget. Analysing housing conditions are the important aspect of measuring material well-being, because they are strongly related to incomes.

The average number of rooms per person has risen over the past decade in Poland and the Czech Republic but is still below the EU average in both countries. It was 1,4 room per person in the Czech Republic and 1,1 room per person in Poland in 2016. Housing affordability worsened significantly between 2005-2010 in the Czech Republic but has remained stable in recent years. In comparison, housing affordability has worsened in recent years in Poland, standing slightly below the EU average in 2016. The percentage of people living in dwellings without basic sanitary facilities has been cut by one-third since 2005 in the Czech Republic and has been reduced by almost a half in Poland in the same period.

In sum, with the increase of GDP per capita and equivalised household income, housing conditions improved both in Poland and Czech Republic but are still below the EU average in many aspects.

### 3.4. Inequalities and Poverty

While median disposable income provides a measure of the typical living standards, devoid of the potential distortion of aggregate measures such as GDP per capita, it still fails to offer the complete picture. Measures of the distribution of income across various economic strata are also needed to depict the extent of economic inequality (Eurostat, 2014, p. 23). Income distribution within societies, income inequalities and poverty are an essential part of measuring people's material well-being, because social exclusion is not dependent on income and poverty only. Accessibility to decent material living conditions, financial security, such as the ability to face unforeseen risks, as well as participation in the economic and social life, are factors which, although often interdependent with income, have to be taken into account. Therefore a more holistic statistical indicator is used to evaluate the material well-being. AROPE, standing for 'at risk of poverty or social exclusion' indicates the number of persons who are (i) either at risk of poverty (as indicated by their disposable income); or (ii) face severe material deprivation (as gauged on accessibility to a standard, objective set of material items); or (iii) live in a household with very low work intensity. 'People at risk of poverty or social exclusion' is one of the best examples of a synthetic indicator; it concerns mainly the dimension 'material living conditions' (Eurostat, 2012).

**Table 1: Gini Coefficient and People at Risk of Poverty and Social Exclusion in Poland, Czech Republic and European Union in 2005 and 2016**

Country	Gini coefficient			People at risk of poverty and social exclusion		
	2005	2016	Change (%) 2005-2016	2005	2016	Change (%) 2005-2016
<b>Poland</b>	35.6	29.8	- 16.0	45.3	21.9	- 51.7
<b>Czech Republic</b>	26.0	25.1	- 3.5	19.6	13.3	-32.1
<b>EU-27</b>	30.6	29.8	- 2.6	25.8	23.6	-8.5

Source: own calculations on Eurostat

As can be observed in Table 1 the level of inequalities in Poland and Czech Republic were very different after the accession to European Union. Inequalities (measured by Gini coefficient) and poverty (measured by people at risk of poverty and social exclusion) were an area of comparative weakness in Poland in 2005. Contrary to Poland, these material well-being dimensions were better in Czech Republic than in Poland in 2005 as well as in 2016. The sub indicators: at risk of poverty rate and the rate of severely materially deprived people are twice as high in Poland (17,1% and 11,9%) as in Czech Republic (8,6%, 6,6%) in 2016. It is worth to notice, that the percentage change in inequalities was 16% in Poland and 3,5% in Czech Republic in the period 2005-2016 (measured by Gini index). The distance between two countries decreased as a result of these changes. The last decade has been a turbulent time for several aspects of inequalities and poverty in Poland and Czech Republic but still Czech Republic is much better than.

Conclusions of comparative analysis of selected material well-being measures state that material well-being was higher in Czech Republic than in Poland at the moment of joining the European Union and in 2016. The GDP per capita and disposable income are still lower in both analysed countries than EU-average. Taking into consideration inequalities and poverty the situation improved dramatically especially in PL and is better or quite the same as the EU-average in 2016. The Czech Republic's performance across inequalities and poverty is much better than Poland's and European Union's average both in 2005 and 2016.

#### **4. Immaterial Quality of Life in Poland and the Czech Republic**

Employability, thus incomes and material wealth have significant impact on human well-being, therefore economists usually pay attention to these categories when assessing socio-economic situation in certain country. However, individuals, as well as policy makers, becoming more aware that immaterial factors also contribute to individual and social well-being. Unfortunately, incomes, wealth and immaterial domains of well-being are closely interconnected.

##### **4.1 Education**

Education is a key element influencing people's skills and competencies and thus their earnings and life-evaluation (Stiglitz, Sen, Fitoussi, 2010). Analysis made by OECD ([online], 2011, p. 20-24) reveal interrelation between attained level of education and other important domains of the well-being: *Better educated individuals earn higher wages and have a higher probability to have a job. Better educated individuals also participate more actively in politics and in the community life, they commit fewer crimes and rely less on social assistance.* In Poland and the Czech Republic, the increasing number of individuals attained the tertiary education, and at the same time decreasing number of individuals attained only lower than secondary education, have been evident since their accession to the EU in 2004 (Fig. 3).

**Figure 4: Population in PL, CZ and EU28 by Educational Attainment Level (in %)**

Source: own calculations on Eurostat

Note: Level 1: Less than primary, primary and lower secondary education; Level 2: Upper secondary, post-secondary but non-tertiary education; Level 3: Tertiary education.

In Poland, more people have a university degree than in the Czech Republic. In 2004, the gap between PL and CZ counted for 2,4 p.p., and for 4,6 p.p in 2016. In contrast to the widening gap between the share of population with tertiary education between PL and CZ, the gap between CZ, PL and EU28 has been narrowing since countries’ accession to the European Union (Table 2).

**Table 2: Population in PL, CZ and EU28 with Tertiary Education (in %)**

Country	2004	2015	Change 2004-2015 (in p.p.)
EU28	19.1	26.7	7.6
CZ	10.4	19.8	9.4
PL	12.8	24.4	11.6

Source: own calculations on Eurostat

However, if only two levels of attained education are observed (below the upper secondary versus upper secondary and above), the Czech Republic is the best performing unit. More individuals reached at least upper secondary education in the Czech Republic than in Poland and EU28 (Fig. 4).

**Figure 5: Population in PL, CZ and EU28 with at Least Upper Secondary Education (in %)**

Source: own calculations on Eurostat

OECD data (2017) confirms that attained level of education has significant relation to individuals' earnings. If the relative income of those with upper secondary education is equal to 100, then income of those with:

- tertiary education is equal to 148 in CZ (in the year 2015) and 141 in PL (in the year 2014), and
- attained education below the upper secondary level is 84 in CZ (in 2015) and 86 in PL (in 2014).

#### 4.2 Health and Health Status

Health is a basic feature influencing the length and overall quality of people's life. Surveys made in many countries consistently found that people put health status, together with jobs to the top of what affects their living conditions. Similarly to education, health status is interrelated with other domains of well-being – having a good job, adequate income, participating on society's life, education, etc. (OECD [online], 2011).

Life expectancy at birth is typically observed in the inter-country comparison. Brief comparison of the level of life expectancy at birth in the Czech Republic and Poland reveals significant difference. In the Czech Republic, on average, length of individuals' life is higher than in Poland, the gap is constant, counted for about 1 year (Fig.5).

**Figure 6: Life Expectancy at Birth in PL, CZ and EU28 (in years)**

Source: own calculations on Eurostat

In Poland and the Czech Republic, life expectancy is lower than the EU28 average. Any significant convergence between CZ, PL and EU28 is not evident, although observed units experienced increasing life expectancies at birth (Table 3).

**Table 3: Life Expectancy in PL, CZ and EU28 with Tertiary Education (in years)**

Country	2004	2015	Change 2004-2015
<b>EU28</b>	78.4	80.6	2.2
<b>CZ</b>	75.9	78.7	2.8
<b>PL</b>	74.9	77.5	2.6

Source: own calculations on Eurostat

Czech individuals also feel more healthy than the Polish ones when their self-perceived health status (Fig. 6) monitored by Eurostat in EU-SILC surveys is taken into account. However, subjective feelings are worse than the EU28 average.

**Figure 7: Self-Perceived Health: Percentages of Population Judging Their Health as Very Good or Good in PL, CZ and EU28 (in %)**

Source: own calculations on Eurostat

### 4.3 Environmental Conditions

Environmental conditions have immediate and long-term impact on individuals' quality of life. They are associated with the sustainability of human's production and consumption. This influence is direct and indirect. Direct impact are observed through existing air and water pollution, while indirect one through changes in water cycles, losing biodiversity and finely through climate changes.

Greenhouse gas emissions are responsible for existing air pollution in European countries. Following European Union's and international commitments concerning the environmental protection, Poland and the Czech Republic have implemented new environmental policies. They have encourage the use of greener technologies in their industrial production and people's consumption. Therefore, since 1990 decreasing greenhouse emissions are evident in CZ and PL, as well as in the whole the European Union (Fig. 7).

**Figure 8: Greenhouse Gas Emissions in PL, CZ and EU28 (in CO<sub>2</sub> equivalent, base year 1990 = 100)**

Source: Own calculation on Eurostat

Progress in elimination of greenhouse gas emissions has been more significant in the case of EU28 than in the case of CZ and PL. However, the Czech Republic is the most successful due to fast structural shift (Table 4).

**Table 4: Greenhouse Gas Emissions in PL, CZ and EU28 (in CO<sub>2</sub> Equivalent, Base Year 1990 = 100)**

Country	2004	2015	Change 2004-2015
EU28	94.04	77.88	-16.16
CZ	75.83	64.90	-10.93
PL	85.20	82.76	-2.44

Source: own calculations on Eurostat

Despite decreasing air pollution, Czech people feel to be more disturbed by pollution, grime and other environmental problems than the Polish ones. In 2005, 19,8% of Czech respondents taking part EU-SILC survey felt disturbed by such problems, while only 13,8% of Polish respondents. In 2015, still less Polish respondents (10,5%) considered environmental problems to disturb them than the Czech ones (13,8%).

#### 4.4 Personal security/insecurity

Stiglitz, Sen and Fitoussi (2010) suggested taking into account external factors such as crime, accidents, natural disasters and climate change when the attention is paid to personal security/insecurity in quality of life analysis. Being afraid of crime has important impact on self-reported well-being status. Crime may lead to loss of life and property, as well as engendering physical pain, post-traumatic stress and anxiety (OECD [online], 2011, p. 32).

It is impossible to base assessment of personal security on official data, because they are not fully comparable across EU Member States. However, OECD analysis confirms that socio-economic inequality measured by incomes and education seems to play a central role in the occurrence of criminal victimization. This phenomenon can be explain with fact that economically disadvantaged people are likely to life in city/towns' districts with lower housing prices but with high criminality and with the lack of the resources enabling them to protect themselves against crimes.

Personal security assessment is based on self-reported status of individuals in most studies. For instance, EU-SILC surveys monitor the share of people perceive crime, violence and vandalism as a problem in the area where they live in. In this field, significant differences between CZ and PL are evident. More respondents feel to be afraid of crime in the Czech Republic than in Poland (Fig. 8).

**Figure 9: Share of People Who Perceive Crime, Violence and Vandalism as a Problem in PL, CZ and EU28 (in %)**

Source: Own calculation on Eurostat

In the Czech Republic, Poland and in the whole European Union declining share of people receiving crime and violence as a problem is evident. However, subjective feeling of personal insecurity is the lowest in Poland.

## 5. Conclusion

The European strategy aims at creating a socially inclusive society and increasing the quality of life of citizens (Eurostat, 2015). Poland and the Czech Republic improved their performance in material and immaterial well-being after the accession to EU. The analysis conducted in the paper proves high importance of multidimensional measuring well-being and showed the diversity between Poland and the Czech Republic according to different dimensions of material living conditions and quality of life. The article highlights the many faces of well-

being, showing the different dimensions of material and immaterial well-being measures. In according to material aspects it covers incomes, inequalities and poverty problems. Our results show that Poland and the Czech Republic had different patterns in terms of different dimensions of material and immaterial well-being.

In the period after accession to European Union the standard of living and quality of life improved. The improvement in material well-being can be observed both in Poland and Czech Republic. The Czech Republic is performing better than Poland in material living conditions and inequalities. Despite the fact that incomes were growing faster in Poland than in the Czech Republic, the level of material well-being (in different dimensions) is still higher in the Czech Republic than in Poland.

The decrease in inequalities and poverty can be observed in these two countries which resulted in better or the same level of material conditions (in inequalities and poverty) as in the EU on average. The reason may be connected with the European cohesion policy which aimed in increasing the material living conditions across the poorest regions in EU. Poland and Czech Republic are both characterized by lower incomes than EU average but the gap between Poland and Czech Republic declined, as well as the gap between Poland, Czech Republic and the EU average in the analysed period.

Material living conditions have significant impact on quality of life in immaterial terms. Therefore, slight differences between Poland and the Czech Republic exist also in analysed dimension of the quality of life. Both countries have made real progress since their entrance to the European Union in all observed dimensions of immaterial well-being and thus EU membership has positive impact on socio-economic development in both countries. However, on average, the Czech Republic performed better than Poland, in some case also better the EU average performance was.

We consider topic of material and immaterial well-being as actual and attractive with the optics of EU cohesion, therefore our further research will be focused on identification of the reasons of differences in defined domains of well-being in EU Member States accessing since the year 2004. We also plan to analyse the the EU membership countries' progress in this field.

### **Abstract**

*This article discusses issues related to the operation of service companies in Poland in the Silesian Voivodship, taking into account their development directions and the most important goals that companies undertake to meet market requirements and improve their market position, taking into account their aspirations to operate on EU market. The author presents the results of research conducted among enterprises in the Silesian Voivodship in which the aim is to depict the motives and ambitions of enterprises wishing to maintain their stabilization on the market and develop their functioning, especially in European Union, in order to gain more clients as well as to build a competitive advantage in the business environment. In the article, the author concerns the advantages coming from the functioning of enterprises in The Internal Market, as well as potential drawbacks which force the entrepreneurs to think globally not only locally if their aim is to stay competitive.*

**Keywords:** *european businesses, internal market, internationalization, marketing, management, service enterprises*

**JEL Classification:** *011, 012, 019*

### **1. Introduction**

The process of internationalization of business activity becomes an important element affecting the functioning of the enterprise in the demanding conditions of the international environment. It plays a huge role in modern entrepreneurship, has an impact on building business strategies and in general, accompanies the ongoing changes in the economic sphere. Nowadays, entrepreneurs have better access to knowledge about foreign markets, and hence, greater opportunities and the chances for these markets to enter with a product and/or a service. Awareness of the business environment supports contemporary internationalization processes, which become an indispensable way to compete with other entities and can be a factor stimulating production growth and thus a factor increasing profits. Both strategic management in enterprises, as well as and internationalization strategies are the foundation of the company's development and orientation to foreign markets. Significant, therefore, is the exploration of approaches and strategic management processes that determine enterprises to expand in connection with internationalization strategies, its instruments and sources, as well as, the key determinants and trends prevailing in the contemporary realities of business management in global conditions. This article aims to examine issues related to the functioning of enterprises in the international environment. First of all, there is a need to define the concept of internationalization and the aspect of functioning companies in EU market. This market is

called The Internal Market (the author uses the acronym IM) as its main objective is to assure that all members of EU have the equal rights in the economic sphere and the conditions of running the business are very much the same in the whole area of EU. Thus, the author suggests regarding IM in terms of a variety of peoples, cultures, and lifestyles which determine demand, customers' expectations, and economic trends. From the EU point of view, 28 members cannot distinguish between German, Irish, Czech or Lithuanian markets as there exists only one common market with the free and undisturbed flow of people, goods, and services. However, for instance, for Polish entrepreneur IM still will show diversity due to the fact that operating in Malta, Italy or Estonia, or any other EU country will be different as different are the people, their needs, exiting trends, clients' wallet wealth, own resources, or even such basic issues as climate or geographical location. In such case, IM may be regarded as the international business environment in which entrepreneurship can be discussed in terms of internationalization. The author, therefore, focuses on discoursing on external and internal factors affecting the functioning of enterprises in international conditions. This includes discussion on the international business environment as the factor influencing strategic decisions, management orientation, and what is more, the key determinants defining the major marketing goals or/and directions of development of the companies (Pabian, Bylok and Kucęba, 2011). Specifically and particularly, the article focuses on service companies and their opportunities to gain benefits from functioning in IM or obstacles that may exist in this matter. If one would consider IM as the convenient and full of business chances field, the companies running their business in different EU countries should bring a number of profits. The question then arises whether the service companies obtain such benefits in the same way as the production or trade entities? And what is more, what are their expectations or how they find themselves in these conditions? Thus, the author of this paper analyses, on the one hand, the level of internationalization of service companies and, on the other hand, their outlooks in terms of profit and loss.

## **2. Problem Formulation and Methodology**

Prerequisites for starting enterprises in the context of the international environment may derive from specific objectives and directions which each company may expect. In order to verify what inclines the Polish service initiatives to go beyond the home market and function in other EU countries, and what the entrepreneurs assume as the opportunity of development, an appropriate study has been conducted. The study was made in 2016 among the Polish companies of various forms of business in the Silesian Voivodeship. It was based on the questionnaire (CAWI and CATI techniques) among 100 entities. In the research sample, there were selected 74 companies which remain as service companies or companies joining services with production and/or trade. Data obtained in the survey and analyzed allowed for drawing key conclusions. The empirical part of the article has been preceded by a deep scientific literature study. The author's aim is to indicate that the international business environment has a significant impact on strategic decisions taken by the entrepreneurs and that in case of service companies foreign markets may become a chance of business development or they may be seen as the limit the companies are not able to exceed. A hypothesis was made that Polish service companies are orientated towards specific goals and development directions allowing obtaining the largest possible number of benefits resulting from the membership in The Internal Market. The results of the research and conclusions may be regarded as the basis for further studies.

### 3. General Aspects of Internationalization

Nowadays, the challenge for entrepreneurs is to function in an international environment, which for many business entities will be an opportunity to gain new sales markets, new clients and making good business relationships. Developing activities abroad may become an asset of the company and effectively strengthen its position in the home country, generate much higher income and improve management skills, which in fact brings huge benefits for the state market economy in the economic dimension, as well as in the political dimension, because presence companies in foreign markets also becomes the showcase of the country from which the company comes. If the company establishes relations with entities outside of its own country, which according to Z. Pierścionek (2003) means "*every form and scope of connections between its various activities with foreign markets*" or, when the company extends production, sales, and additional activities, including research and development works on foreign markets, we are dealing with the internationalization of the company (Jarosiński, 2012). The simplest and original form of internationalization of enterprises is export and import, and the most advanced step is a thorough transfer of production abroad (Pietrasieński, 2005). There exists a number of scientific theories and related topics with the activities of enterprises in the international environment. The theoretical basis for internationalization of the enterprise includes the theory of the technological vulnerability (Rymarczyk, 2004, D. Ricardo, 1951) which assumes that those states gain which engages resources in the production of the selection and services where they have the advantage of the product lifecycle. R. Vernon (1996, 1971) in his theory of international trade suggested the mechanism in which the company first builds up the power of export, then the production begins abroad, next the production is gaining competitive position and finally the competition occurs in the import of the home market (Świerkocki, 2011). According to B. Ohlin (1993), countries will strive to specialize in the production of these goods and services for which they could use their own resources. Furthermore, the theory of cost comparative (Kojima, 1982, Budnikowski, 2003) was based on the supposition that the benefits of the international exchange of goods and services are bilateral when on the side of one of the exchange partners there are significantly lower costs of production of goods. Another concept was developed in the theory of monopoly advantage (Hymer, 1970) suggesting that if there exists any international exchange, it is conditioned by the possibility of using foreign monopoly advantage, for example, due to lower production costs abroad than in the home country (Kosińska, 2008). It is also worth mentioning the theory of currency areas which was proposed by R.Z. Aliber (1976, 1984) who claimed that the differentiation of prices and exchange rates in each country, the size of the market and the costs of starting up foreign operations affect the essence and mechanisms of internationalization. A. Buckley's (2002) (the real option theory) suggested the use of the assets of the company in internationalization for example, for export, franchising or licensing, in which a company partner closer to the foreign market will be able to efficiently and properly determine the opportunities and options for the implementation of selected projects. However, a company with direct investments and thus direct access to the foreign market can independently and better identify and assess opportunities and options profitable from the point of view of undertaking projects. The fundamental issue of the theory is to estimate the maximum net current value of direct investments, taking into account the actual options for each form of internationalization (Bowman and Moskowitz, 2001). In addition, the eclectic theory of foreign direct investment is also distinguished, indicating the need for three reasons for undertaking an operation on foreign plaster: an advantage over others, using advantage for themselves and not for others through the sale of a license or its lease, and easy access to the market, favorable location (Witek-Hajduk, 2010). Theories in various ways draw attention to the factors or prerequisites for enterprises to make decisions about internationalization. It is impossible to ignore in these considerations, the network theory, which defines the company as a fragment of a larger whole,

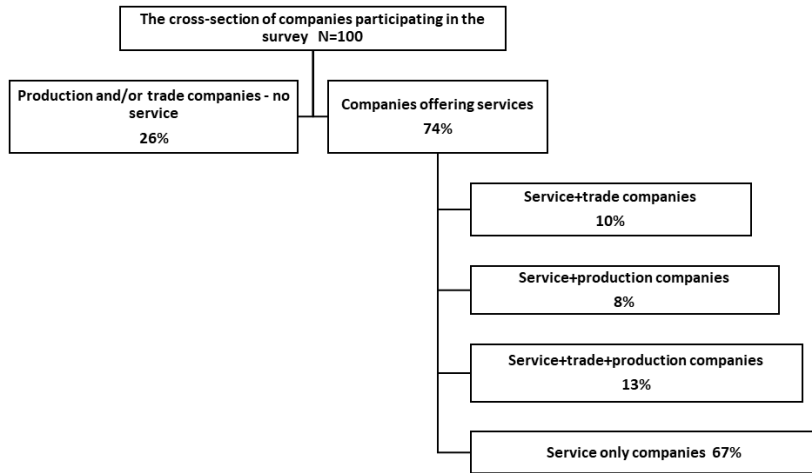

a system in which all involved interact with each other, are interrelated. Enterprises in the network remain in vertical relations within the adopted value chain, and in horizontal relations with competitors. In a more advanced network model, relationships with the business environment reach, for example governmental institutions, financial institutions or companies involved in advertising campaigns. The above theories have become the basis for developing models and levels of internationalization of enterprises, strategies, and methods of entering foreign markets used by enterprises oriented towards internationalization processes. In modern times globalization processes are naturally present in the activities of enterprises regardless of their size. Businesses that are active and developing in terms of consumer expectations are fully aware that the modern consumer "thinks globally" and expects access to products from around the world. Therefore, the company should naturally expand its business in such a way as to meet the diverse and complex needs of consumers. One of the ways to enrich the offer is, precisely, cooperation with a foreign entrepreneur or direct access and activity on foreign markets to meet the expectations of foreign markets consumers and / or simultaneously at home in the country (Chrzan and Kowalski, 2009, Fojtiková, 2013, Ślusarczyk, 2013, Baláž, 2014). In the course of internationalization, it is worth focusing on the factors and motives affecting and conditioning a range of activities undertaken by enterprises, especially service ones. From many different factors, the way of internationalization of enterprises and the undertaken action strategies on foreign markets, both those existing inside companies and external factors, including the international environment, which enterprises must consider taking into account and achieving competitive advantage in other countries will depend on. Themes of internationalization of operations are basically similar to the motives of the enterprise functioning in national conditions. However, while a company operating solely in its own country should take into account the national environment, a company oriented to foreign markets must take into account not only the national environment, but also the international environment. Some motives will opt for the realization of high profits, but others will initiate conditions so that profits can be achieved at all. The motives for the internationalization of enterprises can be comprehensively divided into economic, market and legal (Wiktor, 1998, Magdolenová, 2010, Madzinová, 2016). It is impossible to omit matters related to border crossing and internationalization in today's economic activity, because it is not the prevailing trend but a real determinant of competitiveness and attractiveness, as well as a measurable success factor. Often a specific exhaustion of demand for products on the domestic market, as well as strong competition, especially from corporations and large foreign networks, forces enterprises to look for other markets abroad, hence the phenomenon of internationalization of economic activity is an alternative and sometimes a necessity for the company to maintain its position market. In the situation in which Polish enterprises are found through the prism of the EU market, The Internal Market gives great opportunities to expand to EU countries due to unified regulations and the free flow of people, goods and services. However, the IM also opens the country and causes a larger and unlimited influx of EU competitors. The service companies such realities may find stimulating or/and problematic.

#### **4. The Results of the Study**

The research included 100 companies of the Silesian Voivodeship. The cross-section of companies participating in the study includes both medium and micro enterprises as well as small and large enterprises employing over 250 people. The vast majority of companies operate without foreign capital (95%). Two companies pointed to the presence of foreign capital in the range from 1% to 20%, and three in the range from 21% to 50%, which is 2% and 3% respectively. There were not recorded any companies with over 50% of foreign capital. There were 74 companies which offer services in their business and 26 companies which have

no services at all. The detailed cross-section of companies participating in the survey is presented in Figure 1.

**Figure 1: The Cross-Section of Companies Participating in the Survey N=100**

Source: Own elaboration (2018)

As it can be seen in Figure 1, the majority (74%) of all surveyed companies are the entities offering services, among which 67% of companies offer only services and the rest combine services with trade or production. Due to the purpose of the paper, the following results will only refer to the group of 74 entities. Among the analyzed companies, the majority of them does service and consultancy (26%), transport (15%) or building and construction services (11%). The details are presented in Figure 2.

**Figure 2: The Cross-Section of Forms of Activity in % Among the Service Companies N=74**

Source: Own elaboration (2018)

A small number of companies operates in IT and industrial manufacturing (both forms of activities were 8%), 7% offers services in real estate. Other forms of business activities were indicated below 5%. This may lead to first conclusions that in case of Polish companies in the Silesian Voivodeship, the service activity focuses mainly on three major forms, among which the biggest one is usually based on multimedia tools, internet or distance relations and thus is easier to offer. Also, in case of building and construction activity, the services may be offered due to special contracts planned and organized in advance. In terms of internationalization, the companies were asked to indicate the market they operate on. The gathered information is presented in Figure 3.

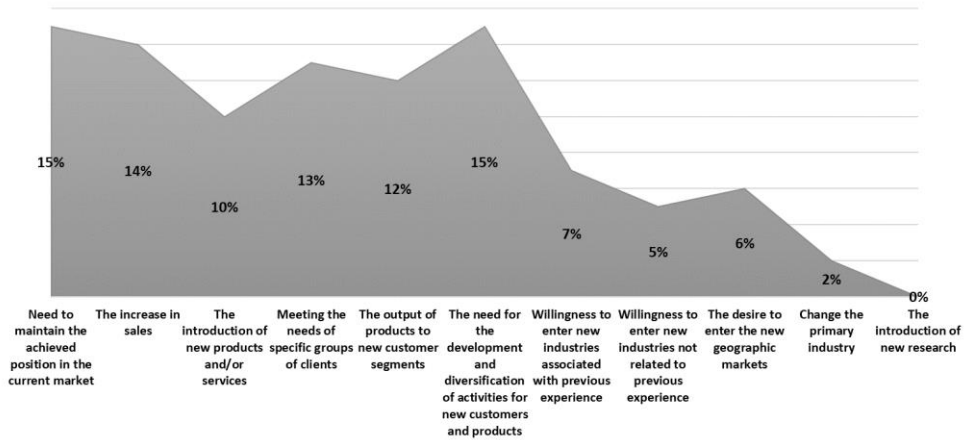

**Figure 3: Focus on Market Among the Service Companies N=74**

Source: Own elaboration (2018)

According to collected data, the majority operates only within the country (36%), 20% chooses rather a local market around city or province, 22% includes foreign markets and 2% functions only on foreign markets. Generally, 75% of service companies from the survey does not operate abroad, which shows that the level of internationalization is rather low – 25% of companies are present on the foreign markets. However, the low level of internationalization does not exclude the fact that the companies cooperate with foreign partners and clients in order to achieve economic benefits. The majority of companies just did not indicate their physical presence with the offer of services outside the domestic market. In further questions about the chief directions of development of the companies and their goals, the companies clearly indicated what they expect from the presence in the international business environment. The gathered information on directions of development of the companies is presented in Figure 4. According to collected answers, companies first of all focus on maintaining their position on the market and they are aware of the need for developing and diversifying their business activity to gain new customers and products. The basic direction of the management of the company is oriented towards obtaining the possibilities to increase sales and to be able to react effectively to clients' needs and requirements, especially of specific groups of clients. Besides, the companies indicated that significant is also the readiness to be open to the new segments of clients and offering new products and services. The minority is likely to change their industry or enter new geographical markets, or new industries connected or not with their business experience.

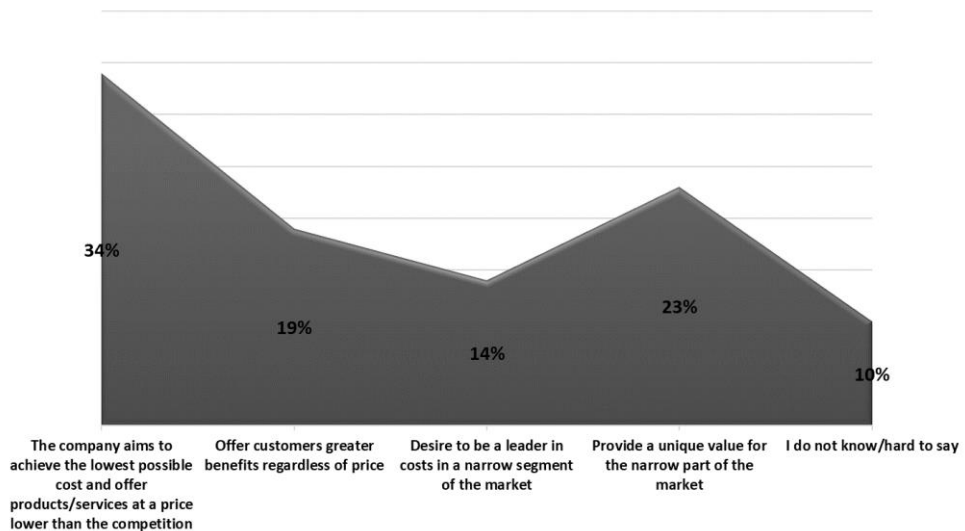

**Figure 4: The Directions of Development of the Surveyed Companies N=74**

Source: Own elaboration (2018)

Developing business by expanding the business activity or broadening the offer in the answer to the expectations of customers should be coordinated with the general goals that the companies usually root in marketing strategies. Such goals were indicated by the surveyed companies in relation to operating of The European Single Market. The results are presented in figure 5.

**Figure 5: Marketing Goals of the Service Companies N=74**

Source: Own elaboration (2018)

The collected data shows that the main goal of the service companies taking part in the survey is focused on being more competitive through cost optimization and offering the services/products at the most attractive price. 34% of companies indicated this goal as the most important one. 23% of the entities want to find its place in a narrow part of the market where they can introduce the unique offer to the customers and at the same time build the company’s reputation. Also, the goal of offering the most beneficial offers to customers despite the price

appeared to be significant, as well, as the aim of becoming the leader in costs in the narrow segment of the market. 10% was not able to precise their basic goals.

## 5. Conclusion

Strong competition and rising consumer expectations force today's companies to look for new markets abroad. There is no doubt that today, precision, quality, flexibility, speed and creativity count in production, services and trade, and that requires appropriate infrastructure, qualified staff, funds for investments, efficient organization and proper culture. Internationalization of enterprises is not so much a challenge today as the potentially enormous benefit and natural process of enterprise evolution taking place in the modern economic realities. In order for companies to be able to find themselves in these difficult and demanding conditions of the international environment, they must be able to define their goals and development directions and act on the basis of appropriate choice of strategy. The conducted study allowed for the conclusion that Polish service companies in the Silesian Voivodeship are aware of that fact and they know in which direction they should go, what goals should be set up and how to function in the conditions of international competitiveness. The results discussed in this paper are certainly just a germ of the research on internationalization, and further studies are recommended and worth conducting in order to learn more about the internationalization of service companies in other regions of Poland or/and in other countries of Europe. Such analysis could help to determine the level of internationalization and the scope of strategies taken by the service companies in the process of entering and operating in foreign markets on a larger scale. The author's credence is that her study could be regarded as the ground step in this matter.

### **Abstract**

*The aim of this paper is to assess and analyze selected three pillars of EU competitiveness and suggest some possible steps forward. As the first pillar of dynamic competitiveness, single market and its size, respectively, are considered. However, some underdeveloped features of the single market persist such as difficult and costly single patent, tax harmonization etc. The second pillar from intertemporal point of view, should be the framework for screening of foreign investments. There are both long-run security and strategic advantage reasons for it. Nevertheless, at present, hardly one half of member states has such a framework. Furthermore, according to ECJ legislation, there is a national competencies supremacy in this field. As the third pillar we assess different types of public goods provision and private goods (creating spillovers) subsidization in the Baldwin-Evenett framework.*

**Keywords:** Baldwin-Evenett framework for competitiveness policy evaluation, foreign direct investment screening framework, single market strengthening

**JEL Classification:** F15, F52, H41, H42

## **1. Introduction**

Competitiveness of the EU in the globalized world is determined by many different features of both – EU Single Market functioning on the one hand and the way, in which the economic policy is made at the EU and member states levels on the other. In our paper we focus on selected, three pillars of EU competitiveness in globalized world. As the first pillar of dynamic competitiveness, the EU single market and its efficiency, respectively, are considered. However, some underdeveloped features of the single market persist such as difficult and costly single patent, tax harmonization etc. The second pillar, from intertemporal point of view, should be the framework for screening of foreign investments. The reasons for it are long-run security and strategic advantage. As the third pillar, we assess different types of public goods provision and private goods (creating spillovers) subsidization from the center or national competencies point of view.

## **2. Weaknesses of the Current Institutional Set-up – Literature Review and Main Findings**

The EU Single Market as a generator of competitive efficiency and of ever growing welfare should have been and have long been the cornerstone of output legitimacy of the whole integration process. What European integration has always lacked in input legitimacy, i.e. the democratic participation on its decision-making and institutional functioning, has been offset by contributions to productivity and welfare attributable to the Single Market, its freedoms of

movement and free and undistorted competition (Erixon, F. Georgieva, R., 2016). Opened symbolically in 1993, the Single Market remains inevitably an “ongoing project” or “work in progress” (Beattie, A., 2017) as differences between Member States that create its barriers are still numerous, and its constantly changing environment, requires a never ending “upgrading” (European Commission, 2015). This never unfinished state of things could still inspire a positive, even optimistic vision of the actual shape of the EU Single Market as it can count on its further step-by-step upgrading and its growing contribution to the EU’s output legitimacy. And for instance, the European Commission’s Communication on the “Upgrading of the Single Market” opens with praise of its achievements in the past 50 years, even though it recognizes its current problems with high unemployment, low levels of growth and investments as well as the size of the remaining barriers.

The Single Market is one of the so-called shared competencies (Article 4 TFEU), i.e. those where, in accordance with the principles of proportionality and subsidiarity, the EU must convince the Member States that, to achieve the Single Market objective, a supranational solution is the optimal one. Until the Member States wish to retain control over direct taxes, social systems, company registrations or civil procedure rules, the EU will not be able to do more than facilitate a voluntary transfer of best practices. Quite logically, there are voices calling for further transfer of competencies from Member States to the EU, the most recent example is the scenario *Doing much more together*, supported as the best option for the EU by the Commission in its *White Paper on the Future of Europe* (European Commission, 2017). Alas, further unification, during liberal times criticized for curtailing regulatory competition between Member States and thus stifling innovation, nowadays crumbles in front of a more substantive barrier: the reluctance of Europeans (Raines, T. et al., 2017).

The free movement of capital, both within the EU as well as to and from the outside world is rightly seen as a cornerstone of the Single Market architecture (Art 63 of TFEU). The general rule however cannot survive without exceptions dictated above all by strategic security interests of the EU and its Member States. The difficult issue thus is to maintain the EU's general openness to FDI inflows and to ensure at the same time that the EU's essential interests are not put in danger. Commission’s President J.-C. Juncker refused in his 2017 State of the Union address to be a “naïve free trader” and explained that in order to defend Europe’s strategic interests an EU framework for investment screening must be put in place.

The right balance between openness and safeguards is for the EU only a half of the issue. The second, equally difficult half, is the extent to which this task belongs to the EU itself or rather to each of the Member States or to an uneasy compromise between the whole and its constitutive parts. Even though under the Treaty provisions on common commercial policy, free movement of capital, control of concentrations and state aids etc. the EU undoubtedly has its say over many aspects of FDIs, the protection of public order, public security and the regime of state or private ownership remain within the purview of Member State competencies. That is why the Regulation (i.e. directly applicable uniform piece of legislation) establishing a framework for screening of foreign direct investments into the European Union (COM(2017) 487 final) has been proposed by the Commission as a very “light” one not taking the decisive say from the Member State to which an FDI is directed, even not forcing all Member State to introduce their own screening mechanism. The new duties consist merely in a structured information sharing between Member States and EU bodies and the necessity to face peer review of investment projects.

The indispensable pillar of competitiveness of nations is also well designed (public, industrial) policy, which includes provision of public goods, merit goods and other measures of industrial policy. What’s more – some peaces of current literature put emphasis on so called international

public goods (international rules for the trade and investment, state bankruptcies, international measures in the environmental field). The EU weakness is relatively small share of common budget on the EU GDP, but the ability to push common rules is more developed.

## ***2.1 Shortcomings of the Single Market***

The EU Single Market efficiency (as well as historical successes) cannot be properly assessed without looking deeper into components (different “free movements”) on which it is built. European market integration was undoubtedly a success in the field of free movement of goods for industry and consumers, as it helped to develop pan-European production chains, but it remains without comparable effects in other fields. Independent assessments agree with the Commission that the free movement of services (especially of digital ones and those provided by regulated professions), of capitals, of labour force, together with differences and loopholes in national tax regimes, are burning issues to deal with if the EU wants to cope with the pressing economic and social challenges. However, contrary to the prevailing optimism spread by the Commission, independent researchers see many more flaws and threats in the overall design, methods and future prospect of the Single Market (Kommerskollegium, 2015).

According to the World Bank Doing Business (World Bank) annual survey, the conditions for businesses on the Single Market still largely differ from one country to another. Denmark ranks as the third best country in the world comparison, while Malta the 84th. Even between the six founding members of the EEC the differences are still important (Germany ranks the 20th, Luxembourg the 63rd) and such a disparity remains more or less constant over the time as the one-decade old results of the same survey can show. In crucial aspects of doing business (like starting business, paying taxes or resolving insolvency) the relative differences are even far more pronounced and the “best” Member States rank among world top ten while the “worst” are around the 120th place. It is thus far from the same to do business in Northern or Southern part of the EU and it is also far more difficult to go over the border if the business is not exporting industrial goods. The services on which 70 % of EU’s GDP and employment depend are traded between Member States with four times smaller intensity than between states of the USA (Aussilloux, V. et al., 2017). There is over 5000 regulated professions in the EU Member States, 25 % of them regulated in only one Member State and qualified specialists, the main agents of the service based economy, thus remain locked in the country of their authorization... It seems that the EU Single Market harvested only low-hanging fruits in the 1990s, while those high in branches, where technocratic neutrality is insufficient because they are substantially more rooted in national traditions and depend on locally specific institutions, processes and discourse, it could not help much yet. Unifying standards for industrial products is a bit easier than unifying the tax base, the functioning of labour offices, or qualification requirements for building surveyors.

This briefly expressed, but statistically well documented (Erixon, F. Georgieva, R., 2016), conclusion brings us back to the question of powers conferred to by the EU by the Treaties and in relation to them to the methods of unification, harmonization or coordination of standards, procedures and institutions that are decisive for the functioning of the Single Market. The EU is not competent to decide on its competences, according to Article 5 of the TEU, it only has the powers entrusted to it by the Member States. As European integration touches more and more on the areas of political struggle and bargaining in the traditional national societies where public consent and political support are a constant necessity, the obvious absence of the European political nation, European political debate, in short of a genuine transnational democracy (Habermas, J., 2015), becomes increasingly visible. Transferring competences to the EU level means emptying the domestic political agenda,

which citizens of individual Member States still regard as their own, while Brussels is seen as the far-away source of binding solutions that leave the national political communities with “no alternatives”. Although this perception is not entirely true, the Brexit vote and the rise of populist parties in many EU countries prove that it has real political consequences. In tax issues, social peace and welfare issues, or in external migration issues (to quote just the most obvious), the EU cannot count on European solutions that would be in a foreseeable future supported by unanimous consensus.

The lack of EU competence to design and develop the Single Market from A to Z, in a holistic manner, inevitably influences the choice of methods and tools that the EU can use to “upgrade” it. The almost full unification through EU regulations is the minority option suitable especially for the short list of the exclusive EU competences under Art 3 of TFEU (namely external trade policy, competition protection and single currency). In the Single Market area other methods and tools dominate, albeit all of them have their pros and cons that complicate the “upgrading”. The most liberal option is that of negative integration pushed forward by the so-called mutual recognition (or country of origin) principle, applied hand in hand with the direct effect of Treaty articles on free movement of goods, services, persons, capitals and businesses (establishment). This option clearly favours regulatory competition between Member States and thus poses a risk of “race to the bottom” in protective standards, if it is not hampered by numerous “exceptions” justified by overriding reasons in public interest of the Member States concerned (Deakin, S., 2006). Needless to stress, that especially “old” Member States do not want to face the cheap and less regulated competition coming from “new” Member States as shown by their pressure to revise the Posting Workers Directive 96/71/EC. The reluctance to accept the country of origin principle leads (especially in the field of professional and socially sensitive services) to its full opposite: the host country (or country of destination) principle, that forces entrepreneurs to cope with 28 different standards and authorization regimes.

The Single Market directives as mere harmonization (not unification) tools seem to offer the so much sought compromise solution as they leave to Member States certain margin of manoeuvre when they implement them to their national legal orders. The problem however is that the minimum harmonization directives do not produce very often the expected results and the Commission (like in the field of consumer or data protection) tends to switch to maximum harmonization principle in order not to let the Single Market fall apart (Gerner-Beuerle, C., 2012). Unfortunately, the maximum harmonization directives resemble so much the regulations (that sometimes are even preferred, like in the case of GDPR 2016/679 Regulation that replaced the data protection Directive 95/46/EC), that they often meet with the same criticism and reluctance at the Member State level. The most important is that these positive integration measures are usually adopted to deal with specific issues (of cross-border relevance) but – due to power sharing with Member States – do not create a brand new regulatory regime that would replace the old one. They rather add another “European” layer of paperwork and bureaucracy that inflate the traditional and persistent agenda of national administration bodies (Erixon, F. Georgieva, R., 2016); (as national tax authorities, trade inspections or employment offices can testify).

In the areas where no EU power to unify or harmonize exist, the Single Market can be completed through the open method of coordination (as in social protection matters) or creation of optional regimes (as the abandoned CESL project – the 28th European Contract Law Regime proposed in 2011), i.e. methods representing a softly guided evolution towards a common standard. Unfortunately, especially in areas where the Member States still prefer their own national solutions, these methods generate rather costs (on research, communication, evaluation) than tangible results and do not lead to a significant upgrade in the Single Market unification. All in all, the EU Single Market finds itself between the rock and the hard place,

when external pressures of globalization push for greater unification of standards, procedures and institutions, but the EU's internal divisions remain so important that in all politically, socially and symbolically sensitive areas (the breaking effect of the language issue in the European patent with unitary protection can be quoted as an example), no progress can be realized soon. Careful, long-negotiated compromises which bothers everyone to roughly the same extent and combine different methods to reach the sought-after outcome are the most probable way forward.

## ***2.2 Deficits of the Present Security Screening in the FDI Field***

A recent illustration to such competences "puzzle" can be seen in the aforementioned proposal of Regulation establishing a framework for screening of foreign direct investments (FDI) into the European Union (European Commission, 2017). Up to now, there is no mechanism at the EU level and the existing national regimes are very different, some Member States do not have any specific screening of FDIs at all. Everybody feels that it is in the common interest to prevent foreign State-controlled investors (especially from countries like China or Russia) to get hold of strategic infrastructure, research or industry assets inside the EU. The goal of the proposed Regulation "to establish a framework for the Member States, and in certain cases the Commission, to screen foreign direct investments in the European Union" therefore stands for itself. At the same time however the Commission must take into account "the existing diversity between Member States in relation to screening of foreign direct investments" (more than half of them do not screen FDI yet) and that the EU cannot impose one standardized solution. The core of the draft thus consists in the common approach to screening and information exchange – for the Member States with their own FDI control mechanism and the obligation of annual reporting - for the Member States without any such mechanism.

Very likely the positive outcome of the Regulation would be the introduction of FDI screening mechanisms in majority of Member States as well as their greater transparency and possibly also their gradual convergence in some aspects. On the other hand, the increased administrative costs and a heavier regulatory burden would inevitably come too. Above all, however, it is not known what the mechanism would mean to investment projects for which Member States compete between themselves (Silk Road Economic Belt projects for instance), or more crucially, to projects that some of them seen as vital and others as dangerous ones (Nord Stream natural gas pipeline through the Baltic Sea is an obvious example here). Needless to say that Member States do not share the same definition of strategic or sensitive sectors (Sunesen E.R., Hansen, M. H. 2018, p. 26-27) and the Commission may carry out a screening on grounds of security and public order on its own, only in case where a FDI may affect projects or programmes of Union interest (like Galileo etc.). Nevertheless, the proposed Regulation is the realistic maximum that can be achieved today.

## ***2.3 Outdated Division of Competencies - Industrial Policy and Public/Merit Goods Provision***

Existing set-up of mutual policies a centralized financing of selected policy fields such as the common agriculture policy (CAP) is, in many cases, given by the historical development. However, from the contemporary point of view it appears to be obsolete. Besides the subsidiarity principle, it barely meets the cost-benefit analysis requirements and it does not reflect such approaches, which represent the Baldwin and Evenett framework. This framework illustrates, that it is worth providing certain public and merit goods with a high level of international mobility from the supranational level. On the contrary, on the national level,

provisions of such goods should be limited. This approach is discussed in greater detail in subsection 3.3.

### **3. Aiming at Increasing EU Global Competitiveness – Reshaping Policies**

#### ***3.1 Reshaping Internal Market Functioning***

With weak public support and the absenting political will the EU Single Market, further developed in the current rails, would not play the decisive role in boosting the competitiveness of EU economies. As the Commission foresees in its *Nothing but the Single Market scenario* of its White Paper on the Future of Europe: “market for goods and capital strengthened; standards continue to differ; free movement of people and services not fully guaranteed... capacity to act collectively is limited; issues of common concern often need to be solved bilaterally” (European Commission, 2017). Should the wealth creating function of the Single Market be enhanced then both the support of the elites and of the general public must be gained. Compromises in politically and socially sensitive issues like taxes, publicly regulated services, social security, energy mix are not however at hand and even the thorough enforcement of the existing Single Market *acquis* by the Commission and the European Court of Justice sometimes sparks fierce controversies as the Brexit history shows. An “enhanced cooperation” of the interested Member States, permitted under the Arts 20 TEU and 326-334 TFEU, would then be the likely way forward in many future developments of the Single Market, as it is nowadays for the European patent with unitary effect and financial transaction tax.

#### ***3.2 Need for Higher Security Protection in the FDI Field***

FDI screening should be further watched and analysed as a litmus test of the EU’s capacity to free itself from the “stuck in the middle” position between an associated State and an association of States when in some aspects it is already very much integrated and in some others not at all. Risks posed by FDIs as manifestations of global challenges should rationally be coped with by the most competent EU acting on behalf of a common interest. In reality, however, the EU today cannot play this role without Member States loyal cooperation and it is to be seen whether external pressures coming from competing powers like China and Russia would push enough Member States together enough to create a more supranational mechanism of FDI control.

#### ***3.3 Designing Modified Frameworks for Public and Merit Goods Provision on the EU Level***

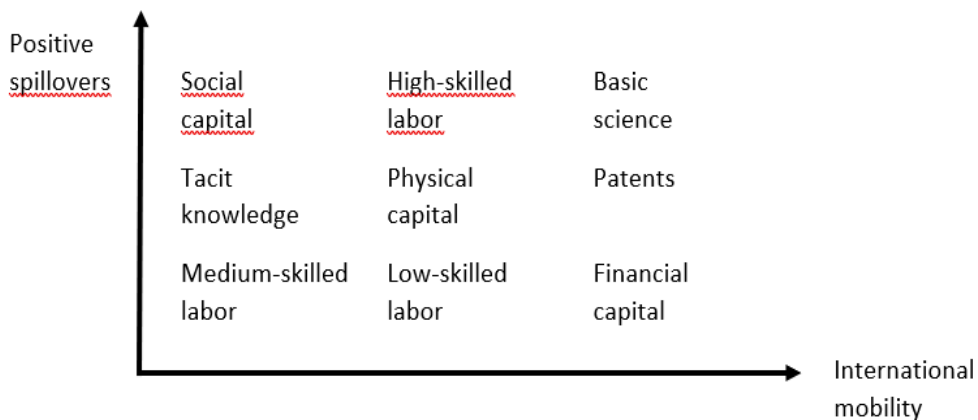

Apart from the description, how complicated an achievement of feasible political consensus at the EU level could be, it is worth declaring, that, not only single market, but an appropriate industrial policy could and should be important for general EU competitiveness in a globalized world.

As Baldwin points out (Baldwin 2016, pp 229) or (Baldwin and Evenett 2015, pp 48, 49) respectively, standard competitiveness policy of rich nations is the promotion of certain productive factors as human capital and/or knowledge capital. The traditional justification of such a policy is a bigger social reward of the above mentioned measures than the private one. This argument is broadly known as a “positive spillovers” argument. But in current economy,

the newly created human- or knowledge capital tends to flow to the nation where their reward is highest.

Baldwin (2016) offers, for purpose of workability of different public policy measures aiming at positive spillovers support, a two-dimensional evaluation framework as follows.

**Figure 1: Two-Dimensional Evaluation Framework for Industrial Policy Measures**

Source: Modified from Baldwin (2016), Figure 55

A clear implication of such evaluation is that international coordination or directly centralization of industrial policy is worth, especially in cases of growth factors which are located north-east in the scheme.

#### 4. Conclusion

To conclude, the EU global competitiveness strengthening could be originated by a more effective functioning of internal market. An “enhanced cooperation” of the interested Member States, permitted under the Arts 20 TEU and 326-334 TFEU, would then be the likely way forward in many future developments of the Single Market, as it is nowadays for the European patent with unitary effect and financial transaction tax. An improved ability to do security screening of FDI inflow with the aim to protect strategic industries (of all member states) against foreign State-controlled investor is needed. FDI screening should be further watched and analysed as a litmus test of the EU’s capacity to free itself from the “stuck in the middle” position between an associated State and an association of States when in some aspects it is already very much integrated and in some others not at all. Risks posed by FDIs as manifestations of global challenges should rationally be coped with by the most competent EU acting on behalf of a common interest. Last but not least, an ability to coordinate industrial policies in such a way that the subsidies with easily mutualized impact should be the matter of appropriate coordination, harmonization or centralization as shows the Baldwin-Evenett approach.

### **Abstract**

*Age structure of agricultural workers in the Czech Republic is not favourable, which can negatively influence the competitiveness of the sector as younger farmers tend to be more open to innovation and more often learn new approaches to farming and business. Therefore, EU tries to support the generation renewal from Common Agricultural Policy funds – from 1<sup>st</sup> pillar and by measures of Rural Development Program. The aim of the paper is to assess the measures supporting young farmers implemented in the Czech Republic. Measures are compared in terms of their conditions and outcomes and their contribution to the policy objectives. Despite the amount of granted money and receivers of the support, the problem of generational change remains. Farmers usually overtake a farm (typically from parents) as starting completely new business is complicated (e.g. due to lack of available land and finances and administrative burden). Therefore, the measures that would help young farmers to overcome the entry barriers shall be implemented too.*

**Keywords:** *Common Agricultural Policy; European Union; Rural Development Program; subsidies; young farmers*

**JEL Classification:** *Q18, H25, J11*

### **1. Introduction**

In the Czech Republic, the share of farmers – managers of the agricultural holdings under 35 years – was lower than 5% in 2013. On the other hand, there were over 33% of managers in age category 55 to 64 years. Young managers of farms represents only 1.2% of all workers (CZSO, 2011) and 25.8% of all managers respectively.

That can negatively influence the competitiveness of the sector as it is possible to assume that younger farmers are more open to innovation and more often learn new approaches to farming and business. Besides, “younger farmers have a longer planning horizon and tend to invest more heavily in business growth than comparable older age groups.” (Davis et al., 2013). They tend to promote more innovations as for example in Hungary, where the Young Farmers' Hungarian Association is proactive in promoting knowledge sharing and, by implication, innovation in farming (Fieldsend, 2016). This is confirmed by Galanopoulos et al. (2011) who found out that older age of the farmers and the lack of successors is often the main reason for

insufficient level of taking over new production technologies and improvement of the management systems, that can be realized only in case of the presence of the returns to scale.

However, young farmers might not be more technically efficient (see Pechrová (2015a)) who found that young and other farmers do not statistically significantly differ in terms of the technical efficiency) as same as it cannot be clearly concluded whether the farms improved after receiving the support (see Pechrová (2015b) who calculated profitability indicators and technical efficiency of 11 young farmers, but ROA, ROE or ROS varied after obtaining the subsidy. She found no statistically significant relation found between the number of years from subsidy receiving and technical efficiency.). Similarly, also findings of Davis et al. (2009) suggest that is any significant differences in performance between farms depending on the age of manager. On the other hand, farmers that are open to sustainable agricultural practices such as organic farming tend to be younger. (Lobley et al., 2009).

Hence, the generation renewal is crucial. Despite that the initial motivator and guide into agriculture for young and new-entrants to the sector is often the knowledge obtained from family, Šūmane et al. (2017) proclaimed, there are certain barriers that hinder the practical entrance to the sector. “Many socioeconomic factors, such as reduced access to land and credit, and lack of rural infrastructure, drive young people away from a career in agrarian sector.” (Rovný, 2016) Besides as found in a study by Zagata and Sutherland (2015), there is a problem of limited opportunities for young people to access agricultural land, particularly in Eastern Europe. Hence, the start-up of the young farmers’ businesses is supported from public funds.

## 2. Support from EU

Support for generational renewal in agriculture is well rooted in the Common Agricultural Policy (CAP) of the European Union (EU). Already McSharry’s reform, adopted in 1992 pointed to the fact that the high number of farmers is old, thus encompassing incentive programs to support retirement, reducing employment or moving farmers to other sectors. CAP currently constitutes of two pillars. While the first one includes direct aid and market measures as well as the payments to be claimed, the second pillar represents mostly project based subsidies. (Pechrová, 2013) Under the 1<sup>st</sup> pillar young farmers have higher direct payments (in addition to the base payment per hectare) and under 2<sup>nd</sup> pillar – Rural Development Programme (RDP) there is a special programme for starting farmers under 40 years setting up their business for the first time. The RDP measure “Setting up Young Farmers” aims to fight the demographic problems of these areas. (Bournaris et al., 2014)

Importance of the support for young farmers in countries of the EU varies in terms of finances devoted to young farmers compared to the total budget of the RDP and the share of farmers with support. Support for generation renewal can be spread within RDP in several measures – M01 Transfer of knowledge, M02 Advisory services, M04 investment, M06 Farm development and M16 Cooperation. For example, Czech Republic provided 57 047 EUR (0.002% of total RDP budget) to measure M01 Transfer of knowledge. Then 30 million EUR of total public expenditures was allocated to M06 Farm development. (Šimpach, 2017). M06 supports the entry of young persons into the agricultural sector by providing a one-off grant to trained young farmers who have set-up in farming for the first time. (Bournaris et al., 2016)

Czech RDP 2007–2014 supported farmers up to their 40<sup>th</sup> birthday, while in current RDP 2014–2020 are eligible also farmers up to their 41<sup>st</sup> birthday. (Šimpachová Pechrová, 2017) The form of the support is investment grant up to 70 000 EUR per one business plan of the young farmer. “The potential merits of such assistance lies in an aspiration to bring into the

industry well qualified younger people who can provide a firmer foundation for the development of a dynamic and competitive sector in the future.” (Davis et al., 2013)

### 3. Materials and methods

The aim of the paper is to assess the measures supporting young farmers implemented in the CR. We particularly pay attention to the measures I.3.2 and 6.1.1 *Setting-up of the young farmers activities* of Rural Development Programme (RDP) financed from EU resources (EAFRD). Both measures are compared in terms of their conditions and outcomes and their contribution to the policy objectives are outlined. Firstly, support from 1st pillar and then from 2nd pillar of CAP presented. We based our analysis on the publicly available data from Ministry of Agriculture of the Czech Republic (MoA) and State Agricultural Interventional Fund (SAIF) and on the data about the amount of standard production of young farmers that were provided by the MoA. The analysis is done from financial and performance point of view.

### 4. Results

Direct payments provided under the first pillar of the CAP has changed and since 2014 consist of seven parts, where the payment scheme for young farmers is mandatory. It is provided in the form of the addition is in the height of 30% of the basic payment and paid to the farmers up to 40 years and new starting farmers or agricultural holdings founded in recent 5 years. It is provided only for 5 years since the foundation and on maximum 90 hectares. Rate in the year 2015 was 885 CZK (25% from SAPS in height 3543 CZK), 878 CZK (25% from 3514 CZK) in year 2016 and the lowest was in 2017, only 844 CZK in addition to 3 375 CZK of SAPS. In year 2015 3 890 of farms was supported which represented 77 650 hectares. In later years, the number of applicants was much higher (see Tab. 1). Hence, average supported acreage was in all years around 20 ha. The share of legal entities increased slightly.

National financial envelope was in all three years 70 mil. CZK that represents around 0.15% of the total finances (SAPS represents almost half of them). Because the support for young farmers did not exist before, it is not possible to assess how many young farmers had been supported in previous years. We can suppose that the number of supported farmers is now stabilized and that there are slightly over 4 thous. of them benefiting from higher direct payments on hectares or livestock unit (LU).

**Table 1: Direct Payments – Additional Support to Young Farmers**

	2015	2016	2017
<b>Total number of applicants - young farmers</b>	3 890	4 273	4289
<b>Total supported area</b>	77 650 ha	84 475 ha	84 364 ha
<b>Average supported area</b>	20.0 ha	19.8 ha	19.7 ha
<b>No. of physical persons</b>	3 724 (96%)	4 050 (95%)	N/A
<b>No. of legal persons</b>	166 (4%)	223 (5%)	N/A

Source: MoA (2017), MoA (2018), own elaboration

Regarding the RDP, between 2007 and 2013, more than 126 000 young farmers in the EU received financial assistance to start operations on their farms, in total amount of 3,65 bil. EUR

(ENRD, 2014). The support is granted based on the submitted business plan and its implementation that provides to some extent a control on the way in which grant aid is invested. Because it is an investment type of support, to assess its effectiveness needs a longer time horizon. Therefore, it is still not possible to assess the effectiveness of the aid provided in the new programming period. Hence, we assess first the subsidies in the 2007–2013 programming period. Under measure I.3.2 *Setting-up of the young farmers activities* 6 rounds of call for grants' applications took place. During the duration of the measure, 3 606 projects were submitted and registered, 1 364 of which were approved and 1 351 repaid till 16<sup>th</sup> September 2015 (see Fig. 1.). Repaid amount was 1.5 bil. CZK (till 09/2015; but 9.7 CZK still had to be repaid). Average success rate of applicants was only 38%. Especially in 12<sup>th</sup> call the it was very low, because there was submitted a high number of applications (731). However, most applications were submitted in 2010. In last round in 2012 was success relatively high (46%) thanks to low number of applications. The most applicants in absolute terms succeeded in year 2009, when in 6<sup>th</sup> round was submitted 391 and accepted 358 applications.

**Figure 1: Number of Registered, Approved and Paid Projects from RDP 2007-2013**

Source: MoA (2015), own elaboration

According to Eurostat, there were 5000 farmers up to 35 years in farms' management. Hence, the program supported 27% of them. Every young starting farmer could get up to 1.1 mil. CZK, but in many cases the applicants requested lower amount. Majority of finances was paid in 2009 in 6<sup>th</sup> round. On average, the most finances per project was spent at the beginning of the 1<sup>st</sup> round. On the contrary, projects with the lowest average value 1 007 450 CZK were submitted in year 2010. Each year the average age was similar, women were on average about 3 years older constantly across all rounds. The highest number of beneficiaries (362) was between 25 and 29 years old. Persons over 30 years of age represented about 47% of sample, persons under 25 years of age 26%. However, the percentage of big farms increased, so if the number of holdings with young managers decreased, the acreage of increased. Despite that, the largest category of young farmers' holding is up to 50 ha (there were 53% of them in 2013).

Predominant type of business remains mixed crop and livestock production, field crops and grazing livestock. The minimal interest of starting entrepreneurs was in individual breeding of pigs and poultry, the milk sector or horticulture, which corresponds to the overall situation in agriculture in the CR – see Ekotoxa and Ireas (2016).

Generation renewal in RDP 2014–2020 shall be supported by financing 750 young farmers. While the aim in previous programming period was 1 500 and so-far 1 364 projects were

repaid, currently it is supposed that there will be 2.86% of holdings with supported development plan or investments. In 01/2018 already 781 projects were approved or recommended. This number can be lower, as not all projects will be repaid. In previous programming period, there were 1375 approved projects, but only 1286 repaid. Nevertheless, the number of approved projects in new period is relatively high considering, that so far only 2 calls for subsidies took place. Similar number of approved projects was achieved in previous period only in the 3rd call. Besides, their number currently exceeds stated target.

So far, there were only two rounds of calls (2<sup>nd</sup> round in 2016 and 4<sup>th</sup> round in 2017). In 1<sup>st</sup> call, there were submitted 682 applications, but the administration was stopped in 141 cases; 507 projects were recommended and 34 alternated. It has been signed yet 538 agreements on providing the subsidies. Hence, the success rate was high – 86.1%. The points awarded to projects ranged from 30 to 96, with an average of 61. Total amount of demanded finances was 685 mil. CZK. Average age of young applicants was 31, while half of the young farmers was older and half younger than 30 years. The youngest applicant was 19 years old, the most frequent age was 26 years. Some farmers (7) did not have any land (they probably run only livestock production), but an average applicant managed around 30 hectares. Only 21 farms were larger than 100 hectares. On the other hand, 79 had less than 5 hectares.

The value of SO was obtained from the appendix of application for grant. Majority of young farmers has small SO. Only few farmers had SO higher than 3 mil. CZK. The prevailing type of production was growing of wheat, permanent non-extensive meadows and pastures, followed by barley. Majority of projects included permanent meadows and pastures and livestock production – livestock up to 1 year. In 288 cases was part of sowing process wheat, in 264 cases fodder crops and in 129 projects appeared potatoes. If young farmers had livestock production, the largest volume of SO consisted of cattle breeding up to 1 year and other cows. The intent to breed cattle appeared in more than 700 projects. In addition, production of goats and sheep for milk production was important. Most projects contained cattle, sheep, goats and equines. On the contrary, the less type was breeding rabbits and poultry.

In the second call were registered 478 projects and approved 240 in amount of 3.75 mil. CZK (3 were denied so far). Originally there were 264 in category Recommended, 61 in category Alternative and 153 was not-recommended. The success rate was around 50%. Average number of points per project was 63 ranging from 52 to 90. There were 150 men and 59 women and 31 limited liability companies. There is no publicly available information about the acreage of the supported farms so far. Also, the SO of farms is not published. From publicly available data, we can see certain trends. Despite that mostly the titles of the projects are “Setting-up of the business”, sometimes they enable to see the type of production. A content analysis revealed that 15 projects were aimed on crop production, particularly of fruit (7 cases from which 3 were for wine production), there was 1 project for barley storage and 1 for processing of beer and 1 for lavender. Mixed production appeared in 6 projects and livestock production in 28. Cattle production was declared in 6 projects as same as goats breeding. There were 4 farms in ecological type of management and 2 were aimed also on horse breeding.

## 5. Discussion

Despite that the measures supporting young farmers is well rooted in CAP, it is very hard to access their real contribution. Authorities usually monitor only the number of applicants (that is relatively high in both programming periods), success rate of the applicants and fulfilling of the target of the share of supported young farmers from all. There should be used more sophisticated methods such as counterfactual analysis which compares the situation of those farmers who took advantage of the support with those who started their farms without support.

However, it is difficult to find matched pairs of farmers. Therefore, simulation models are used. Davis et al. (2013) used dynamic farm-level optimization framework of the model and find out that New Entrants Scheme which will assist younger people who wish to set-up in farming had a significantly more positive impact than Early Retirement Scheme. But e.g. in Greek,  $\frac{1}{4}$  of 254 respondents claimed that they have regretted participating in Young farmer policy scheme. “The most frequent reason... is that this policy scheme was highly promoted, creating this way higher expectations than the real potentials.” (Kontogeorgos et al., 2014).

The problem of death weigh of the policy tools is also well known and discussed for example by Doucha et al. (2017). Also, Balmann and Sahrbacher (2014) highlight that subsidies reduce scope of action for future policies. It is quite usual that young farmers would start the farming activities even without support as they “have to” overtake the firm from their parents or they wish to continue in the family business. In this case, financial support for investment plan is facilitating the process, which would happen anyway.

Another situation is in case when farmers start new firm which is harder due to entrance barriers (lack of soil or credit possibilities) and not related to young farmers only. Ingram and Kirwan (2011) described, how setting up long-term arrangements enables the new entrant to “buy into” an existing farm business and gradually taking over managerial control in Cornwall, United Kingdom, but found deep-rooted reluctance towards participation in joint ventures. This type of taking over the farm is not used in the CR and probably does not represent a feasible way. Support for young starting-up farmers, therefore, seems as the only possible way so far. Despite that the amount of finances will shrink, with declining population of farmers, could be sufficient. A projection elaborated by Šimpach and Pechrová (2015) shows that while in 2011 it there were 12.1% of young farmers (potential applicants for subsidies) supported by 205.7 bil. EUR, this amount will be able to cover 18.6% of young farmers in 2041.

## 6. Conclusion

The aim of the paper was to assess the measures supporting young farmers that were implemented in the CR. We focused on measures from CAP and directly aimed at those farmers and are financed from the means of the EU. In both programming periods (2007–2013, 2014–2020) the interest of young applicants was high. Hence, the success rate was only 38%, 67.3% resp. It is therefore interesting why the MoA choose to support only 750 in current programming period, while the target in previous period was set on 1500. At that times it was achieved from 87% (1300 projects were supported). Currently already around 780 projects are approved to be funded and there were only 2 rounds of calls for subsidies so far, while in previous period there were 6 of them. Hence, the set goals will be probably exceeded.

Besides, farmers usually overtake a farm (usually from parents) as starting completely new business is complicated (due to lack of available land and finances and administrative burden). Therefore, the measures that would help young farmers to overcome the entry barriers shall be probably implemented too. Besides, so far, the financial support did not succeed too much in attracting young people to livestock production (as it is desirable according to the strategies of agricultural sector proclaimed by the MoA). Hence, this shall be also considered.

Nevertheless, our focus was only on measures from CAP and directly aimed at young farmers. There are other possibilities, such as Farming and Forestry Relief and Guarantee Fund that provides grants on interests of investment loans with higher rate of support to farmers younger than 40 years. Besides, many measures influence the decision of young farmers also indirectly – such as measure *M04 – Investment to tangible assets*, operation 4.1.1 (agricultural

investments) and 4.2.1 (food-processing investments) of RDP 2014–2020. Hence, the challenge for future research is to examine the subsidies in broader context of other measures.

### Abstract

*The aim of the paper is to find out whether the intensity and effectiveness of innovation contributes to measuring creativity and innovative approaches to the company portfolio. In contribution was presented the innovation policy EU, new approaches and innovation changes in Procter & Gamble. The study is divided into two specific parts – the theoretical and the analytical part – in order to verify stated hypothesis that stands: The use of complex system of innovation evaluation contributes to the successful product implementation. The following methods were used in the theoretical and analytical part to analyse the present contribution: analysis, synthesis, comparison, observation, questionnaire and interview. Basing on the results of the analysis, it can be concluded that the hypothesis has been verified. Without the complex evaluation system, the probably time-to-market indicator of the newly developed or innovated products/services would be continuously increasing alongside with the amount of innovative ideas, as the consideration in terms of one metrics are not sufficient for the purposes of innovation potential which is conditioned by the quality of human resources and the organization's capability to run more parallel innovative international projects.*

**Keywords:** changes and new approaches, EU innovation policy, innovation process, Procter & Gamble

**JEL Classification:** M21, O32, O50

### 1. Introduction

The importance of an EU innovation policy for employment, competitiveness, environment, industry and energy is to transform research results into better services and products, maintain competitiveness on the world market and improve the quality of life of European citizens. The aim of the EU innovation policy is to create a framework to bring new ideas to the global market.

According to (Boscoianu, Prelipcean, and Lupan, 2018) innovation can be the result of a partial business activity or research activity, the purchase of know-how, patents, utility and industrial designs and licenses. How to say (Evans, Vladimirova, Holgado et al., 2017) a stimulus for creating new organizational directives, and measures with the support of modern information and communication technologies, particularly the internet and social networks (Kulyk and Škodová Parmová, 2017). The continual innovation in compliance with the development of

the market and feedback from company's stakeholders is nowadays necessary in order to gain or maintain the competitive advantage within the market sector (Schuhmacher, Kuester and Hultink, 2018). The innovative approaches to the production are commonly associated with the permanent analysis of the possibilities of improvement that are based on the overall and complex assessment of consumers' needs and expectations (Pianta, 2017). The aspects of implementation of new or modified products/services across the organizational structure of the company are the key subject of innovation process (Davids and Frenken, 2018). The management of innovation basis on detailed strategies and models (Grubb, McDowall and Drummond, 2017) that describe procedures associated with the development and following integration of the new or modified products/services into the production process (Smith, Gilbert and Sutherland, 2017), including the monitoring and assessment of the innovative impact via stated metrics, says (Sölvell, 2018). The innovation itself is then after seen as a part of the complex process that stands on the launch (Slowak and Regenfelder, 2017). When quantifying the customer value, the magnitude of the benefit is calculated as a measure customer satisfaction that is based on the optimization principle (Bolli, Renold and Wörter, 2018).

Innovation in the business area is associated with creation, development and implementation of new approaches (Straková, Kucharčíková, Pártlová and Váchal, 2016). An idea may be a novel recombination of old ideas, an invention that challenges the present order, or an unprecedented formula or approach (Shalley, Hitt and Zhou, 2015) and (Varkoly et al., 2016). Standard business innovations vary in several characteristics, such as level of novelty, size, complexity, or time period of development (Hrazdilová, 2009). Innovation is defined as both, the outcome of the creative actions and also the process that leads to the innovative solution (Valenta, 2001) and (Vokoun, 2017). Therefore, it can be said that *"an innovative outcome involves the successful application of new ideas, which results from organizational processes that combine various resources to the end. Its objectives are to produce positive results for organizations and their employees, customers, clients and partners – such as growth, profit, sustainability, and job security – with better and cheaper products for the customers, and personal satisfaction for its contributors"* (Dodgson, Gann and Philips, 2014, p. 5).

The classification of innovation provided different ways and styles investing and firm innovation, e.g. how to say authors (Christensen, 1997), (Al-Hakim and Jin, 2010), (Gericke, 2013), (Dodgson, Gann and Phillips, 2014) and (Sayili, Yilmaz, Dyer and Küllü, 2017). However, the innovation always leads to specific type of change that is integrated into the organizational structure and processes (Al-Hakim and Jin, 2010) and (Sroufe, 2017).

Contribution presented EU innovation policy, changes and new approaches in company Procter & Gamble. Procter & Gamble is an international corporation targeted on the production of various kinds of household products and services of every-day use, predominantly comprising detergents and fabrics, and cosmetic products. The company has been grounded in 1837 in United States and had become a globally established producer with a variety of brands since. The basic European single market sector, the company has been oriented on, comprised especially soaps, nowadays the portfolio includes also hygiene products or electronics which are supplied to more than 180 countries all around the world.

### ***1.1 Innovation Process and Changes***

Innovation process is a complex set of actions that aims on managing of the changes that are believed to lead in more profitable and customer-oriented solutions (Kim, 2017). The main focus of innovation management concludes several areas that can be defined as follows in (Dodgson, Gann, Phillips, 2014, p. 13):

1. dealing with disruption – unexpected events that have to be considered in terms of business that the organization has to take stand to through innovation,
2. integrating of innovation process – which is considered to be very diversified as it involves various parties into the development actions (contributors from the organization or outside with various type of occupation, skills, abilities, capabilities and knowledge),
3. managing intangibles – especially knowledge and intellectual property of the organization,
4. encouraging creativity and playfulness – in order to enhance the organizational performance.

Innovation processes and strategies about (Dodgson, Gann, Phillips, 2014), (Hrazdilova, 2009) or (Shalley, Hitt and Zhou, 2015) are defined in a various tools and approaches in accordance with the type of innovation involved.

### ***1.2 Innovative Ratings and Metrics***

Evaluation and control of innovation is a specific process focused on the determination of the impact of innovation on the potential profit of the organization. The common way of providing the metrics to the innovation process is stating of specific aspect of the innovation that is measurable. Often these kinds of measuring are focus on the financial aspects of the production and sales. However, the areas of innovation metrics can be considered very broad in terms of indicators, as the innovation can be provided in a range of operations included within the organizational structure (Christensen, 1997). The common purpose of utilization of the innovation metrics lies in the correlation of the impact of innovation on the internal and especially external business priorities of the organization. The measurements associated with the innovation are therefore useful to provide comparison of the organization in objective on following levels formulated (Trias de Bees and Kotler, 2011, p. 214-215) to other companies within the market sector and ranking among the competitors in order to put a value on the innovation capacity; two or more business units within the organization and measuring of the growth of innovation capacity over time, i. e. to provide the comparison to the previous state of the company's business.

The areas, the innovation metrics targets on are variable, however, they can be categorized according to the dominant aspect of the business and production / service providing of the organization. Within these categories can be included according to (Trias de Bees and Kotler, 2011, p. 216-221):

1. **Economic metrics** – the measuring of the impact of innovation on positive or negative results within the economic area of the organizations business the sales from the new (innovated) product launch – as a percentage of sales of the product to the overall sales in defined time period (commonly 3 to 5 years); profits from the launch of the new (innovated) product – the value for calculation considers only profits on the sales of new product as percentage of the whole profits in 5 years period; company sales from innovations other than the new product – the percentage of sales of other products on the whole amount of products sold; cost savings from innovation – measured in monetary units or a percentage of margin or EBITDA (earnings before interest, taxes, depreciation and amortization); total ROI in innovation – calculation of returns on all investments in innovation in stated time period.
2. **Intensity of innovation** – quantifies the actual value of innovation on the baseline of the product or portfolio before implementation number of patents – the actual number of intellectual property rights needed to be applied for the protection of the

- innovation; number of innovations in product, services, customer experiences, processes or business models – the count of innovations that are provided within stated time period; number of brands – is the marketing equivalent to the number of patents utilized especially in sectors with short-time life of the brand; number of ideas generated per year – calculating the number of all ideas including the ones that have not become an innovation project generated by the employees per year; number of innovation projects in the pipelines – monitors the counts of projects that are solved or within the company during stated period (commonly 3 years). The declining count signals the reduction of innovation in progress, number of on-going innovation projects – is count of projects that are going to be provided and predicts the intensity of innovation in the short-term period as well as the capability of the organization to carry out the projects simultaneously, investment in research and development – measured as a percentage of monetary units on the whole billings of the company per year.
3. **Effectiveness of innovation** – is a metrics considering the relation of profits on the use of all resources of the company (the ratio of inputs and outputs) success rate in new products – the percentage of all new products that prove successful, i.e. that are profitable or stable on the market. The successes of the product can be measured also by using extended criteria stated by the company itself; time to market – predominantly utilized in sectors and industries based on fast technological approach to the competitiveness. The measurements are calculated as a time period of the process of innovation development from the basic idea to the product launch; average investment per project – is an indicator calculating the total costs spent on the research and development projects divided to the count of innovations launched. The indicator is monitored per time period and states the effectiveness of costs on the competitiveness of the portfolio; average impact of investment per successful project – stated as the total investment in research and development divided to the total count of innovation projects (successful and unsuccessful); average expenditure on rejected ideas and projects – stated as costs spent on the projects that did not fulfil the objectives and indicates the capability of the company to halt the innovation projects before they achieve too high investments; number of years as the industry leader – is an indicator of the capability of the organization to innovate in a sustainable manner.
  4. **Culture of innovation is a category for measuring the creativity and widespread of innovative approaches** percentage of employees that produce innovative ideas – on the total count of employees; percentage of employees that assess ideas – on the total count of employees; rate of ideas per employee per year; percentage of time spent on innovation – the rate of working hours of participation on innovation projects on the total count of working hours of all employees per year; number of departments that innovate on an on-going basis; propensity of risk-taking – calculates the count of decision-making with stated level of risk.

## 2. Methodology and Objectives

The study of approaches and issues to the innovation process in Procter & Gamble will be divided into two specific parts – the theoretical and the analytical part – in order to verify stated hypothesis that stands: Intensity and efficiency of innovation contributes to measuring creativity and innovative approaches to the company portfolio.

The theoretical part will be therefore focused on two important topics comprising the characterization of innovation process; its approaches, European innovation policy, strategies and models; and the aspects of assessment with the focus on the metrics commonly utilized.

The analytical part will then after aim on the case study. The case study will be targeted on the complex innovation process within selected company and will evaluated the dependence of the models and strategies utilized in association with the topic on the basis of the economic metrics describing the impact of the innovations implemented.

The following methods were used in the theoretical and analytical part to analyse the present contribution: analysis, synthesis, comparison, observation, questionnaire and interview.

The analysis was used to elaborate the theoretical part of presented paper. We came from a critical analysis of information sources addressing the issue of innovation process. Through synthesis, we have summarized the most relevant information. We used international scientific monographs and contributions, the current date and resources, bringing the latest information about the innovations, changes and new approaches to building customer value in European Single Market. All scientific resources used are referenced.

The analytical part of the contribution is based on observations and interview. The observation took place from January to September 2017, and all Procter & Gamble's innovative product, services and branding strategy especially innovative ideas design were targeted, impacting the market and being noticeable by the mere eye of the customer or potential customer. The outcomes of the observation were summarized through a short questionnaire survey amongst the customers of the analysed company. The purpose of the questionnaire survey was to find out if customers are aware of the innovation activities of the company, whether they feel that innovation activities have a positive impact on them, what is their assumption that the innovation activities of the company are being realized. A questionnaire survey was conducted between 546 economically active persons with gender balance with a higher proportion of secondary-educated employees versus undergraduates in the ratio of 3/2 in the company Procter & Gamble in terms September 2017 in Uherské Hradiště.

An interview with the project manager of the company (man, age: 41, university education, praxis for 9 years with managing projects) in whose competence are innovative projects was used to understand and then describe the innovation process in the analysed company leading to the elaboration of the presented case study. This interview was held in October 2017 in Prague. This was an unstructured interview based on the findings of the questionnaire survey conducted among the customers of the analysed company.

By comparing and synthesizing the results, data and information, we have come to confirm the formulated hypothesis and to formulate suggestions and recommendations leading to the improvement of the present state of the problem solved. These outputs were submitted to the respondent project manager and subsequently to the management of the company and are presented in discussion and conclusion of the contribution.

### **3. New approaches in Procter & Gamble**

#### ***3.1 The Innovation Changes in Procter & Gamble***

The innovation policy within selected company has been built for more than 175 years and is continuously improved to comply with the state-of-the-art approaches utilized globally. The approach to the innovation management within the company has been for a long-time based on the fourth model those targets on the cooperation among the stakeholders of the organization, especially the consumers (via feedback) and suppliers in European Single Market. Such innovation policy is approach however relies on the establishment, maintenance

and improvement of the research and development department and its experiences and expertise. Since 2000, the company has adopted new approach in innovative process ideas identification open innovation changes. Open innovation is built, as it is cited (Ozkan, 2014), on the principle of utilization of external sources during the innovation process, as the expansion of information and communication technologies limits the capabilities of the closed research and development structure of organization to properly react on the changes of market conditions (Fernandes, Cesário and Barata, 2017). The concept of innovation strategy adopted by Procter & Gamble is characterized as a transfer from research and development to connect and develop. This means that the internal research and development department cooperates with the external experts and innovators outside the company in order to spread the innovation potential of the brands. The management of the innovation process, however stayed principally unchanged, the organizational structure has been only supplemented with the managerial approaches and strategies that lead the coordination among the internal and external experts.

Nowadays, more than 35 percent of new products of the company have originated outside the internal research and development department; however, the innovation process is still led and provided inside. For the initial phase of the innovation project development, the company has established an internet-based platform allowing the innovators to enter the proposals to innovation of the products and their solutions that are constantly analysed and implemented into the innovation process database to be considered as a further step in the development process. Moreover, the open innovation approach has been supported by the creation of partnerships between the company and other business or governmental bodies, including manufacturing, research, development, business, scientific centres and organizations and universities.

### ***3.2 The Innovation Process Evaluation and Implementation of Products/Services in Procter & Gamble***

The evaluation of the innovation process proposed and developed is provided in two basic key points. First of them is the assessment in the initial phase of the project. As the sources of ideas are very broad, the company has had to establish an organizational body that evaluates the potential of innovation proposals entered by the platform system, as well as within the partnerships enclosed. At this point, the evaluation is predominantly based on the combination of three areas of innovation metrics – the economic, intensity and effectivity indicators. On the basis of the indicators selected, each idea is evaluated in terms of the impact on the potential competitive and business growth of the company.

After the potential is approved on all three levels, depending on the source of the innovation idea, the company launches the innovation project either on the basis of managerial command or the partnership agreement. The start of the project is then after followed by the stating of project plan and schedule that is applied throughout the whole innovation process.

The evaluation of the innovation process is based predominantly on the level of economic and intensity metrics, and partially on the effectivity metrics (in terms of time-to-market indicator). The economic metrics comprise especially the monitoring of the investments into the research and development process and the overall comparison to the return on investment indicators. The intensity is measured on the basis of monitoring of the successfully launched new products during the stated time period.

This complex system of evaluation of the innovation in both key points, i.e. the idea transferring to the project and the aspects of the success of the project, are applied predominantly for the purpose of the selection of products with high potential of

implementation and quick ROI, and also the monitoring of project course in order to recognize the need for improvement to the project plan.

#### 4. Conclusion

Innovation management presents an important part of the managerial approaches within a global corporation, as the contemporary environment within all kinds of industrial and market areas is highly competitive due to the development of information and communication technologies that have significantly affected its nature. The creation and sustaining of the competitive advantage in EU countries is therefore strongly depended on the innovation strategy adopted that has to be continuously adjusted according to the consumer behaviour of the target customers.

The contribution of innovation process and the incorporated evaluation marketing strategy has been provided on theoretical and analytical level. The theoretical part has focused on providing a base for the further case study of selected enterprise and comprised the research on the topics of innovation and its position within the organizational structure, strategies and models commonly adopted within the organizations including the particular evolution of their historical development and the metrics predominantly utilized to provide the control and monitoring of the innovation process.

The analytical part has been then after targeted on the verification of stated hypothesis: **Intensity and efficiency of innovation contributes to measuring creativity and innovative approaches to the company portfolio.** This hypothesis has been confirmed.

For the purposes of the analysis, the EU innovation policy and strategy approaches of international corporation Procter & Gamble have been selected. The analysis has been primarily based on the general description of the company's business and target consumers, and as well on the specification of the innovation process that has been recognized as the open innovation concept adopted especially due to the conditions of the market environment within the target sector. The basic principle of this concept lies in the involvement of external experts to the process of innovative ideas design and their further development within the innovation process.

Such concept can be considered very demanding especially on the aspects of innovation evaluation and measuring as the potential count of the ideas gained this way can be very high. The first key point of the evaluation request has been recognized in the pre-initial project phase – the selection of the idea to be approved for implementation. The second key point of evaluation is stated within the actual innovation process based on the development of courses of defined indicators. The complex system of evaluation, i.e. comprising the combination of metrics in economic, intensity and effectiveness area, can be therefore considered highly necessary for the purposes of the growth and sustainability of the organization within the competitive EU market environment, as it provides the quick selection of the innovative ideas and recognition of their potential.

Basing on the results of the analysis, it can be concluded that the hypothesis has been verified. Without the complex evaluation system, the probably time-to-market indicator of the newly developed or innovated products would be continuously increasing alongside with the amount of innovative ideas, as the consideration in terms of one metrics are not sufficient for the purposes of innovation potential which is conditioned by the quality of human resources and the organization's capability to run more parallel innovation projects (Chowhan, Pries and Mann, 2017).

The key to future survival and competitive ability of businesses is the development of innovative, information and communication technologies and the ability to take positive changes, notably in customer care and customer value building, through innovative products/services. The company's competitiveness is the unique value of the products/services offered. Achieving a level of competitiveness is the main reason for choosing a successful business strategy.

The questionnaire survey conducted in September 2017 showed that website design, branding, customer and after-sales service updates (postage warranty expiration) changed, increased marketing budget, increased news coverage, news coupons, and sponsored events. Economically active employees have spoken out for innovative changes processes in company Procter & Gamble that they welcome.

Innovation measurability factors have been noted in the increased number of patents and published professional articles, reduced complaints and customer complaints, increased profit margins, increased number of new ideas for products/services/processes (economies of scale), but also suggestions and changes in personnel processes investment in training and recruitment of skilled workers with an emphasis on cross-curricular activities such as time management, MBO, assertiveness, social and diplomatic behaviour and negotiation, presentation and communication skills, purchasing negotiations, financial management for non-financial managers but strategic management).

The international company Procter & Gamble examines the process of collaborating on developing new products/services with local and national educational institutions to develop knowledge and ability to build partnerships with key suppliers (accelerating delivery of individual products/services, setting optimal payment conditions, support EU innovation policy and strategy win - win, close co-operation with vendor on acquisition credible and available information on new or upcoming products/services, an affordable innovation pricing policy); modifies, changes and innovates production, technology, business and marketing processes in EU countries (to compare prices with competitive e-shops, to monitor and confront the results with current competition, to submit and to propose non-traditional ways and forms of promotion (loyalty programs and competitions, discount coupons, commission system, alliance forms of cooperation); supports staff development personnel; adopts new organizational decisions; actively communicates about the particular needs and requirements of key customers, especially on the regional and local markets in EU countries; addresses potential customers through websites and social networks (visitor ratings). Looking ahead, Procter & Gamble should focus more on predicting, identifying opportunities and competitive threats, and on economic returns on investment. Furthermore, it should consider the calculation of the failure rate, for example, in the development or sales process, for example, by increasing revenue for a given segment over a defined period.

In order to change the trend of the EU's innovation policy, Europe needs to make the world's scientific excellence, removing barriers to innovation, such as market fragmentation, slowing down standards, over-patenting, inefficient public-private cooperation, low participation in innovation partnerships between European, and regional institutions and business entities, but also a low level of practical skills of peoples.

Investing in research, innovation and technological development, 3% of GDP would create 3.7 million jobs by 2020 and annual GDP would grow by € 795 billion by 2025. Reforms of EU Member States' education, research and innovation policies create a new space for job creation, the production of goods and services to ensure the sustainable growth of the EU economy.

### **Abstract**

*This article focuses on the issue of brownfields, especially on possible ways of obtaining funds for their regeneration. In the Czech Republic, according to expert research, there are 10-12 thousand abandoned buildings and complexes. Brownfields deal with the Ministries (the Ministry of the Environment, the Ministry for Regional Development and the Ministry of Industry and Trade), which offer the public and private sectors the possibility of obtaining funds for the regeneration of abandoned buildings and complexes. Another way to obtain financial support for brownfield rehabilitation is from European funds (The Business and Infrastructure Support Program, the Investment Plan for Europe and the Real Estate Program). The aim of this paper is to present possible ways of financial support for brownfield regeneration in the Czech Republic. The contribution will be based on examples of good practice of regenerated brownfields in the European Union, supported mainly by European funds.*

**Keywords:** brownfields, EU funds, European Union, regeneration, private sector

**JEL Classification:** O18, R11, R51, R58

### **1. Introduction**

Abandoned objects and areas or brownfields are nowadays a very serious problem not only in the Czech Republic. The term brownfields define each country, respectively these institutions in different ways. With the relative subsidence of settlements and sufficient free space, the definition primarily focuses on contamination such as Denmark. In addition, countries with a relatively high population density and larger areas have, in the definition of the term, mainly the development aspect of brownfields. These include countries such as Belgium, the Netherlands or the United Kingdom. The National Brownfield Regeneration Strategy (2008) or previously Alker (2000) define brownfield as the real estate property (land, building or ground) that is insufficiently utilized, neglected and might be also contaminated. These properties occur as remnants of industrial, agricultural, residential, military or other activities. It is obvious that nowadays when plenty of global, economic, social and environmental challenges that are linked to the sustainable spatial development of cities and municipalities are being solved. The problem of regeneration and re-use of brownfields might at least partially contribute to the solution of these problems (Krzysztofik et al, 2016). One of those primary problems is to reduce the undesirable increase of extent built-up areas on city limits to the account of the open landscape, when brownfields in inner cities are being abandoned and left unused (Maly and Mulicek, 2016). Indeed, boosting support for brownfield regeneration might also contribute to more sustainable development of cities and rural municipalities from the perspective of their physical compactness, generally to increase of social responsibility for our

behaviour and to follow environmentally friendlier tendency to prefer utilization of existing properties over those that are being built on greenfields (De Sousa, 2003). Laforzezza et al., who argue that “brownfield remediation requires special attention to ecological and visual preference effects because these areas are often derelict, undervalued, or misunderstood” (2008, p. 258), this paper takes the view that community perceptions of landscape quality must be systematically investigated and integrated in the regeneration schemes.

The EU is a heterogeneous unit with significant disparities between its Member States and mainly among their regions in many areas of the modern economy (Hančlová et al., 2015). European Union funds represent a tool for realizing European economic and social cohesion. It allocates funds to reduce economic and social disparities between regions. An important point is to efficiently use funds from European funds. The programming period 2014–2020 holds lots of opportunities to fund innovative ideas and projects. The architecture of European funds and direct grants continues to offer a wide range of funding opportunities in the EU Member States. However, funding is often not used effectively or it may be denied due to poor planning. The problem of brownfields in the countries is that these areas and objects are not economically competitive for regeneration compared to green areas without public intervention. The economic, environmental and social barriers present at the site frequently hinder returning brownfields to beneficial use. The European Union and its member states provide different public incentives to make brownfield regeneration more attractive but rarely consider their sustainability (Thornton et al., 2007).

## **2. Possible Ways to Fund Brownfields Regeneration**

Brownfields in the Czech Republic are mainly concerned with the Ministry for Regional Development, the Ministry of the Environment and the Ministry of Industry and Trade. The problem of abandoned buildings, facilities and their possibilities for regeneration is also addressed by the CzechInvest government agency, which supports the use of brownfields for business purposes. The government agency has developed a national brownfield regeneration strategy which estimates that there are approximately 11,700 abandoned buildings and sites in the Czech Republic that cover a total area of 38,000 hectares but an actual number and size may be larger (Turečková et al., 2017).

As part of the general perception of brownfield issues, a variety of funds and operational programs are being targeted to support the revitalization and regeneration of abandoned buildings and sites that can favourably affect not only the environment but also help preserve the architectural character of the site, in the midst of brownfield regeneration, the living standard of the population and the economic situation of the city or village where the brownfield is located. Regeneration of brownfields is a relatively expensive matter. It is often the case that each regeneration phase is funded from other sources. Funding entities have always same expectations, it is some kind of return on the funds injected. Funds for funding may come from investors, developers, banking institutions, such as grants and subsidies. Resources for regeneration can ultimately be combined.

The following part will be devoted to financial resources that can be used for brownfield regeneration and reclamation. The first of the possible sources for the renovation of buildings and areas is the use of bank loans. The owner (public or private) may apply to a bank for a revitalization or reclamation loan where it is adequate to provide the bank with any guarantee that ensures lower interest. Another possible way to raise funds is to fund the regeneration or reclamation of brownfields from the Structural Funds and the Cohesion Fund. In the case of brownfields in this case, there is a need to have set wider and more beneficial priorities in order to achieve structural funding from individual Operational Programs. Funds are fundamental

instruments for promoting social and economic restructuring in the European Union. They are primarily used to balance regional disparities and support regional development through infrastructure and telecommunications development, human resource development and R & D support. Another way to raise funds is to use national programs to restore abandoned buildings and areas. Each country has national funds to support national goals, which may include infrastructure development, social housing construction, health and education facilities development. Brownfields have some degree of flexibility in managing land, which is good for national funds. The next possibility of financial support is risk investments to brownfields. Investors require low or no guarantee, but aim for higher returns than banks. When investing in brownfields, the yield must be higher, the longer it takes to determine what is necessary to do.

### ***2.1 Financing Regeneration of Brownfields from National Programs***

The following subchapter will focus on possible ways of obtaining funds for regeneration of brownfields from national programs in the Czech Republic. In 2016, the National Program for the Support of Regeneration and Business Utilization of Brownfields was approved by the Ministry of Industry and Trade. The main objective of this program is to address the issue of brownfields occurrence in the Czech Republic. For the regeneration of brownfields, a financial amount from the state budget of CZK 2 billion is earmarked for the period 2017-2023. The regions and municipalities that are located in regions of structurally affected regions (Moravian-Silesian, Usti and Karlovy Vary Region) and the economically problematic regions according to the "Regional Development Strategy for 2014-2020" can apply for funding. Subsidies are provided through direct support. The financial support is provided up to 85% of eligible projects expenditure. The above support is intended for the regeneration and reconstruction of brownfields, their transformation into modern business entities and the creation of newly renovated business areas up to 10 hectares. Another national program dealing with brownfields is the program to support Business Real estate and Infrastructure. This program was launched in 2005 and has been extended until the end of 2020. Funds from this program can be used to eliminate environmental burdens or soil contamination on brownfields. Beneficiaries of the subsidy may be municipalities, associations of municipalities, regions, state enterprises, state contributory organizations and the state's organizational unit. The minimum amount of eligible costs is CZK 1 million, and the amount of support is up to 75%.

The Ministry for Regional Development has its own national programs to support rural development and rehabilitation, where funds can be earmarked for the restoration of abandoned buildings and sites. The financial means of these programs are very small compared to the total state budget funds, yet they can reduce regional differences. International programs provided by the Ministry for Regional Development is the Subprogram Support for Rural Renewal and Development. The program has several subsidy titles such as support for cooperation of municipalities for the reconstruction and development of the countryside, support for the restoration of small religious buildings in the municipalities, etc. Applicants have already received subsidies of CZK 481 billion, which were divided into 1022 projects.

### ***2.2 Financing Regeneration of Brownfields from European Funds***

Another part of the contribution will be addressed by the European Union Structural Funds, which can be used for the restoration of abandoned and dilapidated buildings or complexes. Programs are co-financed by the European Structural and Investment Funds for the period 2014-2020.

These programs are linked to the headings set at the national level, from which national development priorities and objectives are based.

The Operational Program Enterprise and Innovation for Competitiveness can be used from the initial programs. The aim of this program is to achieve a competitive and sustainable economy based on knowledge and innovations. Under this program it is possible to draw funds from the Real Estate subprogramme. The program no longer supports constructions of non-agricultural or farmer fields, but only the reconstruction of old buildings and their transformation into modern business premises. Part of it is a demolition of original buildings and subsequent construction of new buildings. Subsidies are provided for the modernization of spatially and technically unsuitable, energy-demanding buildings that can be reused for the development of production activities and services. The condition is that the reconstructed property is not located in the capital city of Prague. Overall, CZK 3.9 billion are earmarked for the Real Estate program for the period 2014-2020. At one object may amount of subsidy funds in CZK 1 - 50 million. The main objective of the Rural Development Program is to restore, preserve and improve the ecosystem dependent on agriculture through agri-environment measures, investment for competitiveness and innovation of farms, support for young people's access to agriculture or landscape infrastructure. This program focuses on rural development, agriculture and forestry. This is primarily a supplementary program, subsidies are not primarily aimed at revitalizing brownfields. The selection of the project can also be considered in terms of possible revitalization of brownfields in the sense of strengthening agrotourism.

The Operational Program Environment is aimed at reducing emissions, increasing energy efficiency and increasing the share of energy from renewable sources. Additionally, this program aims at contributing to the protection, preservation and development of natural resources of the European Union, the creation of a green and competitive low-carbon economy that is efficient use of resources and to protect citizens from environmental pressures and risks affecting their health and safety. The program primarily focuses on the remediation of seriously contaminated brownfields where risks to human health and ecosystems are proven. According to the author of the paper, the biggest problem is the contamination of soil and groundwater at former brownfields, formerly used for the heavy, manufacturing and chemical industries. Heavy contamination is expected here. For former agricultural buildings, the degree of pollution of soil and groundwater is moderate. The program for applicants for subsidies is set at € 2.6 billion. The area associated with the revitalization or recultivation of brownfields can be used up to 800 million Euros.

The following program on how to raise funds for this issue is the Integrated Regional Operational Program. This program aims to promote increased competitiveness and exploitation of the economic potential of the regions, mitigate the deepening of regional disparities, strengthen environmental sustainability and optimize the institutional framework for regional development. Brownfield projects are based on specific objectives (improving the quality of accessibility of services leading to social inclusion and enhancing community-led local development to improve the quality of life in rural areas and activation of local potential) implemented within the Local Action Group Local Development Strategy. The table below shows the amounts of funding for the regeneration of industrial and military sites that could be drawn from structural measures in the 2007-2013 periods. It can be said that from all the Member States of the European Union, the Czech Republic has the second largest financial support for the regeneration of industrial and military brownfields. During this period, EUR 372 million was allocated to the regeneration of brownfields after industrial and military activities in that country. The possibility of obtaining financial support for brownfield could be requested by business entities and municipalities. If entrepreneurs demonstrated economic activity, they could obtain funds for the regeneration of these buildings, mainly for

the reconstruction and remediation of the land. Eligible costs could include business entities as project documentation. In addition, municipalities could ask for subsidies, but their number was of little interest compared to the private sector. A total of € 3.3 billion has been earmarked for this period.

**Table 1: Regeneration of Industrial and Military Brownfields from Structural Measures**

Member state	Allocated amount (EUR)	%	Member state	Allocated amount (EUR)	%
Hungary	475 191 832	14.0	France	90 193 437	2.7

The following table shows the funds allocated to brownfield regeneration and the main Member States concerned. These are two program periods between 2000 and 2006 and the 2007-2013 programs, with Germany, the United Kingdom and France being the main beneficiaries for the first time. For the second period, they were among the largest beneficiaries of EU Member States that joined the EU in 2004. Among the first two countries with the largest allocation were Hungary and the Czech Republic.

**Table 2: Revenue from Structural Measures for Brownfield Regeneration**

	2000 – 2006	2007 – 2013
Allocated funds	<b>2,3 milliard EUR</b>	<b>3,4 milliard EUR</b>
Main recipients	Germany, United Kingdom, France	Hungary, Czech Republic, Germany, Romania.

### 3. Examples of Regenerated Brownfields

The following chapter will focus on examples of good practice of brownfield regeneration from an abroad, supported by funds from European funds.

An example of good practice is the regeneration of brownfields in Olomouc, which was financed from European subsidies and from the Regional Operational Program of the Central

Moravia Cohesion Region. This is the regeneration of a former sawmill in Olomouc part of Bělidla, formerly of Moravian-Silesian woodworking plants with an area of over 24,000 square meters (2,4 hectares). The revitalization started in 2014 and was completed in 2015. The revitalization of the brownfield was the transformation of the abandoned area into the construction of a shopping center, which will be spread over the area of 2.4 hectares. A shopping mall is a supermarket with smaller business units.

A subsidy from the European Union was granted for revitalization of the brownfield, amounting to a maximum of 60% of the total eligible expenditure. The remaining 40% is intended for the regeneration of the brownfield from its own sources of project financing. The table below shows the subsidies provided for the revitalization of the brownfield in Olomouc. Ineligible expenditure amounted to CZK 38 million. The total amount for the revitalization of brownfields in Olomouc was CZK 114 million, where CZK 45 million was mediated from the European Union, mainly from the Regional Operational Program of the Central Moravia Cohesion Region.

**Table 3: Financing Regeneration of Brownfields in Olomouc**

	Resources of the Regional Council - subsidies		Recipient own resources	
	Maximal CZK	Maximal in %	Minimal in CZK	Minimal in %
<b>Investment</b>	45 401 300	60%	30 267 534	40

Source: Revitalization brownfields, Olomouc

The following part of the chapter will focus on examples of good practice from abroad in the context of revitalization and regeneration of brownfields, which have been supported by funds from the European Union. The first example is a former mine in Belgium. This is the C-min in Genk where there were three mines that employed up to 7,000 miners in the 1990s. There are 65,000 inhabitants in the city and the mining mines are located in the immediate vicinity of the city. The area of all three mines with adjacent plots is 3.5 hectares. After the mining activities were completed, the site was revitalized and subsequently left unused. Rebuilding started in 2005 and the site was used from 2010, when the complex was rebuilt into a cultural and educational event. The total cost is around EUR 8.917 million, when the project was funded under the Limburg Objective 2 Program 2000-2006 and the Flanders RCE Program 2007- 2013. The reconstruction costs were financed not only from the city's own budget and programs, but also from the European Fund for Regional Development. Under this program, the brownfield regeneration amount was set at EUR 3.178 million.

Another example is the regeneration of brownfields in Poland, especially in the post-industrial area of Nowe Gliwice. The area of the building is 415.86 hectares and the total area of the brownfield is 97.9 hectares. This site was formerly used as a former coal mine in Poland. The regeneration of the brownfield was focused on building a business incubator, business zone and regional training. The implementation of the project was focused on soil remediation and reclamation. Another reconstruction of the site was the reconstruction of historic buildings after mining. An industrial zone for possible business units was also built. The total amount for reclamation and regeneration was EUR 24.2 million, where EUR 9.51 million was financed from PHARE and EUR 14.69 million from the local budget of Gliwice. The regeneration of brownfields took place from 2005 to 2009.

## 4. Conclusion

The issue of brownfields has been a very serious issue in recent years. Especially in West European countries, the professional public has been interested in this issue for several decades. In the Czech Republic, the brownfield phenomenon has been solved in the last 25 years. The revitalization of brownfields in EU countries has been dealt with since the 1960s and in the Czech Republic since 1990. The aim of the contribution was to identify possible ways of financing the regeneration of brownfields from national European funds. Nowadays, there are many ways to get money for the regeneration and reclamation of abandoned buildings and complexes. These funds can contribute to the development of individual cities and Member States in the European Union. The most abandoned buildings and areas are found mainly in the central and eastern part of Europe. The EU member states are trying to support the construction of various developmental and other business plans, mainly on brownfields. Abandoned buildings and sites are in some ways a weak point and a threat to towns and municipalities in the individual Member States where they occur because they reduce the development of the regions, especially their financial aspect of the public budget. On the other hand, it can be noted that the management of a used brownfield, which has a certain potential, can contribute to the development of the regions and increase not only the economic and living standards. The big issue is the ownership of abandoned buildings and complexes. The public sector has a better chance of regenerating brownfields than the private sector, as private owners do not have either financial means to regenerate or are not interested in rebuilding the brownfield. A possible way is combined ownership, which can contribute to cooperation and potential agreement to restore an abandoned building or complex. If a given owner (public, private or combined) brownfield decides to regenerate brownfields in cities or municipalities, and his potential intention is operational, he can achieve higher revenues than build the same plan on greenfields in the outlying parts of cities. The contribution included examples of brownfield regeneration in the Czech Republic and abroad. All of these examples have the same idea, namely to eliminate the occurrence of abandoned buildings or areas in the cities and to increase economic growth, the living standards of the population and, last but not least, the creation of new jobs. It is important to look at abandoned buildings and sites also from an environmental point of view, as contaminated brownfields can affect the quality of soil and water and can also be dangerous for local residents. These include, in particular, possible injuries and the risk of pathological phenomena. An important consideration for all EU Member States should be to avoid and eliminate other possible brownfield occurrences in individual countries and to prevent the construction of business and development projects on green meadows. Cities are about to grow in and not into the fields.

### **Abstract**

*The article focuses on the analysis of selected social and economic characteristics in order to assess the dynamics and state of convergence of the European Union. This process will be judged in the light of changes in socio-economic differences between today's Member States. The author sees it as essential that social and economic cohesion in the sense of reducing disparities is the right way to ensure the further development of European integration. The status, changes and mutual differences in the social and economic environment of the European Union's members are assessed using the following indicators: total fertility rate, crude rate of net migration, ageing index, female life expectancy at birth, GDP per capita in PPS, consumption of electricity per capita and human development index. Spatial dynamic typology is performed on all selected indicators using the cluster analysis method. The result is primarily evaluate the nature and weight of the process of social and economic convergence of the European Union countries after 1990.*

**Keywords:** cluster analysis, convergence, European Union, socio-economic differences, spatial dynamic typology,

**JEL Classification:** C46, J11, J13, J14, R23

### **1. Introduction**

We live at a time of profound and deep social and economic changes. In general, disparities in the world have long been deepening in all the basic pillars of human society development, for which we can regard the environment, human society and economic development. The main factor of the differences is the human society that is behind the deepening of the social and economic differences in the world. We can assume that the natural environment is a system superior to both the already mentioned systems, ie social and economic. However, we can not at least at the regional level ignore the strong impact of human activity on natural systems (eg, industrial activity, construction, transport, recreation, etc.). Major changes in the core fields of human life are related in particular to processes of globalization, integration and regionalization. These processes are most consistently spreading through economic development and then social development. Evidence of this is the existence of many dozens of economic integrations and a large number of bilateral economic agreements. However, today, a number of serious social differences can not be dealt without a wider and often even global approach. Let's mention the most serious areas for the sustainability of social and economic development:

- health area (civilization diseases, vaccination issues, health checks),
- demographic transition manifestations (population aging process, fertility reduction, family crises, growth of individuals' households, growth in social services, the need for sustainable social policy, differences in life expectancy, etc.),

- equality of gender (processes of feminisation, violence, marriage, partnership, etc.),
- the influence of religion on society's development (Christianity, Islam, atheism, etc.),
- security (protection of citizens' health and life, the right the personal protection, etc.),
- political environment (corporate governance, democracy issues, justice systems, personal freedoms, social policy, etc.),
- strengthening and deepening the industrialization process (new technologies, the production and consumption of electricity).

If, for many millennia, it was true that a better basic living conditions brought about a regional deepening of the complex organization of human society, it seemed that this potential had exhausted itself. Many globalizing effects point to the need to change the behavior of human society. This means changing the approach to solving spatial problems, political issues, social, economic and natural aspects. The current change in the economic environment, often referred to as the arrival of the Industry 4.0 phase, brings a whole new perspective on the relationship between the global and the regional level in the exploitation of the potential of new technologies. In the thousand years of historical development of our society, the key role of its development has played mainly the disintegration processes. As an example, we can point to the emergence of new states with better opportunities to manage the overall management of society, their social and economic development, including increased territorial security.

Certainly, the overwhelming majority of regional experts agrees that deep and deepening economic and social disparities lead to a decline in society's development and, above all, reduce the security of citizens themselves. The process of reducing imbalances in human society today can be considered very important. And this desirable process is certainly helped by the moments of globalization, integration and regionalization. That is why we decided to put the assessment of the European Union's integration process in relation to its future to the analysis of several selected moments of social and economic development of society. Based on a number of factors, we predict that a better future for Europe and European civilization is associated with deepening the process of co-operation within the European Union. We stand for this claim despite all the current serious crisis moments a referendum on the UK's departure from the European Union, the bad economic situation in Greece, the absence of a common migration policy, discrepancies in the area of forming a single monetary union, partial differences in the political culture of the members of the European Union with an impact on different approaches to the issues of social policy of the state, disintegrating state-building manifestations (Catalonia, Northern Ireland, Scotland) or political efforts to raise questions about the possibilities for leaving the European Union (eg referendum).

It is beyond question that under the current level of technological development in the world and especially in Europe deep economic cooperation is necessary. Social cooperation (social policy, social law, national issue, population issues, the position of men and women in society, migration policy, family policy, housing policy, etc.) and security are equally necessary. These two parameters are often the subject of expert debates on population growth and global stability and security in recent decades (Polunin, 1998).

Based on knowledge of demographic transition, and under the impact of economic development on reproductive behavior, we are of the opinion that the issue of population growth today is not the problem, but that the problem is deepening, or rather, not reducing economic and social disparities. Although the warning of population growth has often emerged from the period of economist T. R. Malthus (Newbold, 2007), we do not think that this is an important moment threatening the stability of human society. On the contrary, we see threats in the deepening of social and economic differences and the underestimation in this context of the essence of the integration process of the European Union as well.

## 2. Analytical Approaches to Studying Social and Economic Convergence

We have chosen to use the dynamic spatial typology method to monitor the convergence of the economic and social environment of the members of the European Union. With the current 28 members of the Union, we have taken the last 25 years for the time being, knowing that in 1990 only twelve members have been integrated. Further expansion in the period under review was in the following waves:

- 15 members in 1995 (Finland, Austria, Sweden);
- 25 members in 2004 (Czech Republic, Estonia, Cyprus, Lithuania, Latvia, Hungary, Malta, Poland, Slovakia, Slovenia);
- 27 members in 2007 (Bulgaria and Romania acceded) and
- 28 members in 2013 (Croatia joined).

It is true that our observation of the social and economic position of the current 28 members of the EU with the aim of showing the influence of the integration process in the sense of convergence of a large number of states has only been a very short history because of a significant expansion after 1990. However, that since 1990, the economic and social cooperation between today's EU countries has been very open and naturally deepening. In particular, due to significant political changes in favour of the democratization of the whole of Europe. We use hierarchical cluster analysis (Kettenring, 2006) to monitor convergence, which at the same time captures 25 years of changes in selected indicators for all 28 current members. The selection of suitable indicators was influenced mainly by the weight: demo-social phenomena, economic forces, living standards and availability and quality of the database.

When processing the data we rely on the data of the national statistical offices of individual European Union members and the Eurostat (statistical office of the EU). We process input data using the statistical and analytical software IBM SPSS (Statistical Package for Social Sciences). To measure the process of differences and the nature of convergence between EU members, we decided to use the agglomerative hierarchical cluster analysis method (Staničková, 2013), which objectively tries to cluster based on differences and similarities for larger clusters (Rupp, 2013). Before hierarchical cluster analysis, we use method of „centre moving average“ for three-year periods for better results.

We will analyse the demo-social environment using indicators that assess the demographic transition and the aging process: total fertility rate (partly complemented by natural increment assessment) and aging index (*AI*).

The indicator of total fertility (*TFR*) documents changes in the reproductive behaviour of the population. Its calculation means assessing the number of live births per woman for the reproduction age. At the value of indicator 2.1, the annual variation of the population size is actually zero by natural increase. It is therefore a stagnation zone. All EU countries are significantly below this level. We can judge the aging process very well by evaluating the aging index over a longer time horizon (Šotkovský, 2012). The formula expresses the number of seniors per hundred children (1):

$${}_{t}AI = \frac{{}_{t}P_{65+}}{{}_{t}P_{0-14}} \cdot 100 \quad (1)$$

We will monitor economic differences by analysing these indicators: crude rate of net migration (2), GDP per capita (PPS) and electricity consumption per capita.

While migration behaviour can also be considered as a manifestation associated with a demo-social environment, yet the crucial part of migration in the EU is economic migration.

$${}_tCRNM = \frac{{}_tNM}{{}_tP} \cdot 1,000 \quad \text{or} \quad {}_tCRNM = \frac{{}_tI \cdot {}_tE}{{}_tP} \cdot 1,000 \quad (2)$$

Gross domestic product per capita uses the EU methodology that works with the purchasing power standard (PPS, €). It is an artificially created currency unit for a more appropriate expression of the volume of economic aggregate indicators in the comparison of national economies. We obtain the data in PPS from the value expressed in national currency by dividing the relevant PPP. The per capita electricity consumption indicator shows the depth of industrialization and household consumption. The process of economic development is still linked to the increasing production and consumption of electricity.

Differences in the standard of living have been decided by:

- female life expectancy at birth and
- human development index (*HDI*).

Because the length of life can be considered as an important expression of its quality, life expectancy at birth is often taken as an indicator of overall maturity. The Human Development Index is a UN tool for expressing the quality of human life by comparing lifespan, education and living standards.

### 3. Social Indicators and Convergence Process

We have selected two indicators to assess the change in demoesocial disparities in the EU population after 1990. The first is an indicator of total fertility rate.

**Figure 6: Spatial Dynamic Typology of Total Fertility Rate of the EU Member States**

Source: author’s calculations, based on Eurostat and national statistical offices data

From our analysis of behavioural changes over the last 25 years, it follows:

- Different behaviour in Cyprus and Malta has been changed to compare with the behaviour of most EU countries. Their present value is about 1.5 (total 19 states).
- However, the difference in this indicator has increased between the remaining nine countries (Denmark, Finland, UK, Belgium, the Netherlands, Luxembourg, Sweden, France and Ireland) and the group of 19 countries mentioned above. For the second group (type 2), the current value is up 0.3 on average. At the beginning of the 1990s, the difference was just over 0.1.

When assessing the aging process, it is clear that we have a total of three groups of differing behavioural states with a tendency to widen the gap. We can leave aside Ireland (type 1), where the aging process of own population is only at the beginning. The countries of Bulgaria, Greece, Germany and Italy have a faster dynamics of the aging process, where they are now around 150. The remaining 23 countries now have a very similar evolution of the aging process

with a current value of around 120. The value of the aging index for the European Union is today as a whole 121 (Šotkovský, 2017).

**Figure 7: Spatial Dynamic Typology of Ageing Index of the EU Member States**

Source: author’s calculations, based on Eurostat and national statistical offices data

From the point of view of the changes in the measure of vitality and aging, it is obvious that for the vast majority the development is comparable without significant differences. Nevertheless, we note a slight increase in differences for both main groups. However, most EU members have very similar developments.

#### 4. Economic Differences Between European Union Countries

To assess the economic differences, we first chose international migration. It is a moment often associated with spatial behaviour, but in most cases the economic situation is the main impetus to international migration.

**Figure 8: Spatial Dynamic Typology of Net Migration of the EU Member States**

Source: author’s calculations, based on Eurostat and national statistical offices data

The migration behaviour of most European Union states (type 2, 24 states totally) is very similar in that the value of their migration growth is very low. Additionally, the crude rate of net migration indicator ranges from zero to 2 ‰. In essence, we can consider the values of the migration balance in Luxembourg on the one hand (annual increments of over 10 ‰) and the Baltic States on the other hand (migration decreases ranging from -4 to -14 ‰). Based on the analysis of the international migration of EU countries over the last 25 years (Šotkovský, 2016), we can emphasize:

- The growth of EU countries due to international migration has long been positive.
- We can label the growth rate as slow for 24 EU countries, if it does not exceed 2 to 3 per mille in the long run.
- Only three Baltic States have lost their own population due to the long-term greater emigration than immigration.

**Figure 9: Spatial Dynamic Typology of Economic Performance of the EU Member States**

Source: author’s calculations, based on Eurostat and national statistical offices data

The most widespread indicator for comparing the economic level or its performance is GDP per capita. Based on methodological recommendations, we have measured this indicator as GDP per capita adjusted to the PPS in euro. Here we can see very well the deepening gap between two large groups of states. Among the economically powerful, we can confidently include all member states from Western Europe (Austria, Netherlands, Belgium, Germany, France and Luxembourg) and Northern Europe (Denmark, Sweden, Finland, Ireland, UK), which is further complemented by some countries of southern Europe (Spain, Portugal, Malta, Cyprus, Slovenia and Italy) and the Czech Republic. The second smaller group of states with weaker economic performance consists of nine states (almost all of the eastern and central European countries). Even in this case, we cannot claim that the Member States are moving closer to reducing the differences in the indicators surveyed. On the contrary, even from all the indicators under review, the biggest deepening of the differences between the EU member states are shown here.

**Figure 10: Spatial Dynamic Typology of Electricity Consumption of the EU Countries**

Source: author’s calculations, based on Eurostat and national statistical offices data

The last evaluated macroeconomic indicator was the electricity consumption per capita (MWh per year). Even in this case, there has been no significant reduction in the gap between the advanced European economies of Western and Northern Europe and the group of seven countries with the lowest electricity consumption (Croatia, Hungary, Poland, Bulgaria, Latvia, Lithuania and Romania) from Central, Eastern and Southern Europe.

### 5. Conclusion

For a comprehensive evaluation of the past 25 years of development and the near future of the European integration process, we have, besides the social and economic indicators, still reached the assessment of the expectation of female life expectancy at birth and the human development index. In both of these evaluations, we found that over the past 25 years, the economically weaker EU states have experienced a slight improvement in both economic and social levels after their entry. So far, we consider the differences in these two groups to be

significant. Therefore, we can consider them as an important cause of a number of problems not only of the process of convergence of the EU countries but also as a significant moment of slowing down the overall integration process within the EU. There are still differences in the life expectancy indicator for the birth of women in both groups (type 1 and type 2) around 4 years. Moreover, the division of states into two groups clearly reflects the greater overall maturity of the former Western European states since the Cold War.

**Figure 11: Spatial Dynamic Typology of Life Expetancy at Birth of the EU Countries**

Source: author’s calculations, based on Eurostat and national statistical offices data

When analysing the HDI indicator, which partly incorporates life expectancy but is further complemented by the inclusion of the quality of the educational process and economic development, two basic groups are more distinct in the dynamic spatial typology. We can say that there is a high and clear match of spatial differences and the quality of the process, as well as the hope of female life expectancy. The only exception is the change of status of Malta, Portugal and the Czech Republic.

**Figure 12: Spatial Dynamic Typology of Human Development Index of the EU Countries**

Source: author’s calculations, based on Eurostat and national statistical offices data

The major problem of improving the integration process of the European Union remains, however, significant differences, especially at the economic level and in the overall development of the member countries (Melecký, 2013). These disparities have a negative impact on the deepening of the cooperation of the European Union members. At this time, it is not too favourable time for EU enlargement with new members, including the five candidate countries (Turkey, Macedonia, Montenegro, Serbia and Albania). Selected indicators for monitoring social and economic disparities among EU members would be appropriate to follow in the long term. They show us very well how the necessary process of convergence between the Member States is taking place. Their tracking shows that a slight convergence is going on, but there is still a clear distinction between a group of more developed countries and less developed EU countries. This is certainly frustrating for both groups and is in our view in the background of the current problems of deepening the development of integration and different views on current key moments (migration policy, social policy, etc.). The difference

between the two groups is not so large in global scale but is sufficient for the development of internal co-operation in all major areas of life (economic, social, political and environmental).

## **Abstract**

*The aim of the paper is to assess digital economy concept included in the Europe 2020 strategy in view of its consistency with the new Internet economy model and meeting challenges arising from the digital revolution. A holistic approach is taken. The literature on socio-economic changes brought about by the Internet is reviewed, as well as EU strategic documents are examined critically. The comparative analysis of assumptions and objectives of the digital economy concept against the Internet economy model is carried out. The main conclusion is that the Europe 2020 strategy doesn't assume any transition of European economy towards the Internet economy as a new socio-economic model and EU digital economy is being built on the traditional sources of growth, such as demand and competition stimulation. The ineffectiveness of the EU actions to improve its competitiveness is so far on a conceptual level.*

**Keywords:** digital economy, digital transformation, Europe 2020 strategy, European Union, Internet economy model

**JEL Classification:** E61, O20, O38, O52

## **1. Introduction**

The problems of deterioration of the EU competitive position are linked to the emergence and rapidly increasing pervasiveness of the Internet since the mid-1990s (Miller and Atkinson, 2014; van Ark, 2014, p. 11). Already at that time the EU had identified main challenges generated by new information and communication technologies (ICTs) and pointed out technological gap existing between the EU and the US or Japan (Commission of the European Communities, 1993, pp. 86-95; European Commission, 1994, pp.12-15). That prompted the EU to start intensive actions responding to the changes in socio-economic model. The endless documents, reports, surveys and studies prepared by the EU or commissioned by its institutions indicate still the same things: the huge potential of ICTs, the need to raise total factor productivity, innovation, competitiveness and economic growth. However, the evaluation of action has been taken so far at the EU-level to boost competitiveness drew largely negative conclusions. This raises the fundamental question about the reasons for those failures. Some various sources of inefficiency of the implementation of the joint programmes are identified, and amongst frequently cited are insufficient financial effort and weak determination of the Member States, despite their formal approval of these measures. However, the problem is likely to be of more complex nature due to disruptive changes in the society and economy development brought about by widespread use of ICTs and especially the Internet.

The beneficial impact of the Internet and other ICTs on an economy and in particular on economic growth has been confirmed by numerous research. The comprehensive review of

relevant research and studies are provided by ITU (2011), ITU and UNESCO (2011). Socio-economic consequences of technological developments in the ICTs field go beyond and are compared with changes brought about by industrial and prior agrarian revolution (Westerman, Bonnet, and McAfee, 2014).

### ***1.1 The Internet Economy – Theoretical Foundations***

The Internet economy is one of notions that has been put to label a new economic and social model. There are also other terms but none of them is commonly used. The name chosen here makes direct reference to the Internet which is widely regarded as a transformative technology due to its exceptional properties. The most distinctive characteristics of the Internet are as follows (Afuah and Tucci, 2003):

- interactivity – gives possibility to interact fast (in real-time), anyone to anyone (people, businesses, many-to-many, one-to-many, many-to-one, one-to-one) synchronously and asynchronously,
- universality - unlimited scope of access (anyone anywhere in the world),
- network externalities – the value of the Internet (and products based on it) increases as the more people (users) connect to it, e.g. the Metcalfe's law says that the value of network equals the square of the number of its users (Metcalfe, 2013) and according to Reed's law, this value grows exponentially (Reed, 2001),
- distribution channel of products and/or information about them – replaces the old channels and extends beyond the traditional constraints,
- time moderation – mitigate time pressure by shrinking and enlarging time,
- information asymmetry shrinker – increases transparency and access to the information for all parties concerned,
- infinite virtual capacity – the Internet gives a feeling of unlimited possibilities due to never ending technological advances in processing speed, storage, computing power etc.,
- low cost and open standard – virtually everyone can use it (cheap, open, easy to use),
- creative destroyer – it has the potential to transform the conditions of competition and whole industries (structure, conduct, performance), create brand-new ones,
- transaction-cost reducer – it is due largely to its properties listed above, and especially universality, distribution channel, low cost standard, and information asymmetry reduction.

The Internet with other ICTs are recognized as general purpose technologies (GPT). This is supported by studies carried out by Hempell (2006), Basu and Fernald (2006), Jovanovic and Rousseau (2005) or Clarke, Qiang and Xu (2015). The Internet should thus assume the features of GTP, which include, according to Bresnahan and Trajtenberg (1995): pervasiveness (spreading to most sectors), technological dynamism (improvement over time) and innovation spawning (complementarities with other forms of advancement). Moreover, the Internet as a network technology (a set of technologies, as a matter of fact) is viewed also as a 'disruptive' technology (Manyika, Chui, Bughin et. al., 2013). It means the capacity to transform the way of life, to change ways of doing old things and business and/or it enables doing things that were previously infeasible and, moreover, drastically alters the status quo by destroying current economic and social structures and creating new opportunities, including entirely new sectors. Thus, the Internet challenges the established order, brings in new types of firm, new business models and plays a profound role in the way in which social and economic activities are organized, coordinated and conducted. The even more important changes are in the behaviour and management of the economy than in the technology. These developments

naturally affect all socio-economic stakeholders, i.e. companies, people and governments. Taking into account Christensen`s (2016, p. 226) findings related to disruptive technologies, one of the factor which may lead towards failure in such circumstances is to rely on the markets demand, inasmuch as the first need is to find new markets. However, as Varian and Shapiro (1999) indicated, the demand side economies of scale are key in the economy driven by network effects, such as the case of information systems and Internet economy. So, the size of the market (demand) is crucial, but it refers mainly to the new products being placed on the new markets. In addition, Afuah (2013) argues that not only the size of network is relevant to its value, but also the structure of a network and the conduct of its users. This indicates the importance of the behaviour and quality issues for economic performance. All these points are in line with Brynjolfsson`s (1993) notice that current institutions and principles are outdated and thus can create bottlenecks in the ICTs adoption, and success in this matter must not simply involve overlay new technology on old processes. The general view of the changes induced by proliferation of information and communication network described Castells (1996), Tapscott (1995), Benkler (2006). They have pointed out, inter alia, influence of network technology on the breakthrough in the functioning of social networks, the whole society and individuals activity, creating diverse production models, such as peer, collaborative production or open innovations. The additional advantage of wide ‘social’ inclusion points out also Perez (2014, p. 7).

The transformation towards a new model is becoming a reality and it is necessary to define this term. The broad definition of the Internet economy laid down by the OECD (2012, p. 25) is as follows: ‘all uses and benefits resulting from the connectivity that the Internet provides’. Its precise interpretation may give rise to difficulties. Moreover, the Internet economy as a new emerging model can be incorrect understood through simple associations with technical progress and introducing new products (goods and services) that could then be brought down to only one sector concerns ICTs. Additionally, interpretation difficulties can be affected by certain simplifications assumed in the popular quantity studies into economic role of the Internet, in which a size of Internet economy is estimated on the basis of only the sector of activity directly linked to development and use of the Internet (such as hardware and software, providing Internet services, telecommunication and activity directly based on the Internet) (Deloitte, 2011, pp. 7-8; Rausas, Manyika, Hazan et.al., 2011, pp. 10-11; Cimochoowski, Hutten-Czapski and Rał, 2011, pp. 11-12).

The author (Talar, 2014) defines the Internet economy as the whole socio-economic system which:

- creates and develops the new industries (so-called ‘new’ economy or Internet/ICTs sector),
- changes the entire traditional sector to operate according to the new principles and create added value on the basis of broad network usage,
- uses the Internet as an open platform to involve all stakeholders in innovation and economic activity (irrespective of their functions in the economy, age, social status, education etc.),
- continuously develops network technologies, thus striving to further develop innovation in the field of Internet and new online technologies and their application.

The Internet and related technologies are still evolving and their ubiquitous usage is constantly growing. Therefore, the full transformative impact of Internet is still to be defined.

## 1.2 Digital Transformation – the Challenges for States

The ubiquitous usage of the Internet, and its impact on virtually all areas of social and economic life, raises the need to apply the same approach (both multidirectional and comprehensive) to support transformations under way. Selective references to these challenges can lead to bottlenecks and hinder the changes, and further threaten efforts and resources have already invested in various actions. This calls for a balanced approach during transformation.

Profound changes in the socio-economic system triggered by digital revolution may occur automatically, but broadband gap and digital divide across the world suggest that it is not always the case. Some researchers have seen an active role of the state in the Internet economy creation and management process. Sukhodolov, Popkova and Kuzlaeva (2017) propose stepwise process of the Internet economy building with strong state interference at each stage (Figure 1). However, they suggest that when the new model will become widespread and start working, the role of the state should be minimised. While the sequencing of all actions of the state raises questions, it is notable that the need for the state involvement in the Internet economy establishment is seen and it includes not only traditional functions of the state, such as regulatory and infrastructure provider, but also the new one like a propagator of the Internet activity.

**Figure 1: Algorithm of Internet Economy Creation**

Source: author`s presentation based on Sukhodolov, Popkova and Kuzlaeva (2017).

The similar approach relating to the strong active role of the state in the Internet economy development is taken by Wu (2017). The main feature of ‘the new entity economy’ (as the Internet economy was called) is high integration of the Internet, virtual and real (i.e. traditional) economy. Its development is essentially dependent on the government involvement, for which many tasks were imposed. These include: innovating production service model, strengthening intelligent manufacturing, optimizing the network support system and strengthening different kind of financial support for enterprises. There is also expected direct state participation in the research and development activity as well as engagement in the promotion of application of all new solutions.

The proposal of Wang and Li (2017) is more far-reaching because it is going to reconstruction of planned economy system. The new economic system induced by digital revolution and called ‘plan-oriented market economy’ is a construct based on: both centralised and democratic planning, big data as a technical tool, platform economy as a institutional and organizational space and state-owned enterprises leading operated platform economy in the competition field. We may disagree with the assumptions of market socialism model, but we cannot defy the economic success of China to date.

The researches cited above explicitly and strongly point out that the new socio-economic environment needs strong state involvement, but the state interference has been controversial issue for a long time now. However, all the points lead to the conclusion that the states are now facing challenges at many different levels and areas. The actions they undertake to meet needs

arising from the current techno-economic reality determine future well-being of citizens. The characteristics of ICTs and their importance, and influence on all socio-economic aspects suggest that we need new institutions, new infrastructure, new behaviours, new organisational structures. The state has its own role to play in this transformation and its pace also depends on the involvement of governments.

## 2. Problem Formulation and Methodology

Taking into account deteriorating competitiveness of the EU in the Internet age and challenges of digital transformation, the research question formulated herein is whether European strategy matching with the new techno-economic environment. The aim is to assess EU digital economy concept in the Europe 2020 strategy in the view of meeting the challenges induced by the digital revolution. The new socio-economic model (called herein the Internet economy model) is the benchmark against which to evaluate. It's been hypothesized that one of reasons for the ineffectiveness of EU actions and measures towards improving its competitiveness has been rooted in the conceptual foundations of an adopted digital economy model and relates to the lack of a holistic approach to the concept of digital economy creation and assumptions about its main drivers.

The study is based on a review of the literature on socio-economic changes under ubiquitous Internet and research papers on digital transformation, critical examination of EU strategic documents and comparative analysis of assumptions of EU digital economy concept against the Internet economy model.

The theoretical background of this study is set out in the first section. Drawing on these, the main attributes of the Internet economy model have been figured out and adopted as the reference parameters. The characteristics of this new model and its creation have been captured in the three key criteria for the purpose of comparison and assessment of the consistency of EU digital economy concept with the Internet economy model. There are the following criteria:

- the very concept of the socio-economic model – in particular, whether it represents radical (disruptive, new quality) or incremental innovation and whether it represents holistic (concerning the whole society and economy, all aspects of life and business) or fragmented approach,
- the extent of the state's role in the digital transformation and the new economy functioning – is it just elimination of market distortions or a wide and deep government interference,
- the kind of government measures and areas their application – in particular which functions the state performs, i.e. the state plays as a regulator, investor, propagator, controller or market agent.

The analysis covers the very concept of improving EU competitiveness defined in the official strategy papers, the EU's approach to adapting to the impacts of digital revolution and actions to tapping the potential of ICTs, the digital economy's role in the whole Europe 2020 strategy and main assumptions and objectives of the digital economy concept under the Digital Agenda for Europe. The research ends with checklist preparation and conclusions.

## 3. Problem Solution

The EU's policy which clearly recognizes the challenges related to ICTs development was launched in December 1993 by publication of the White Paper called 'Growth, competitiveness, employment'. Notwithstanding its title, the growing problem of

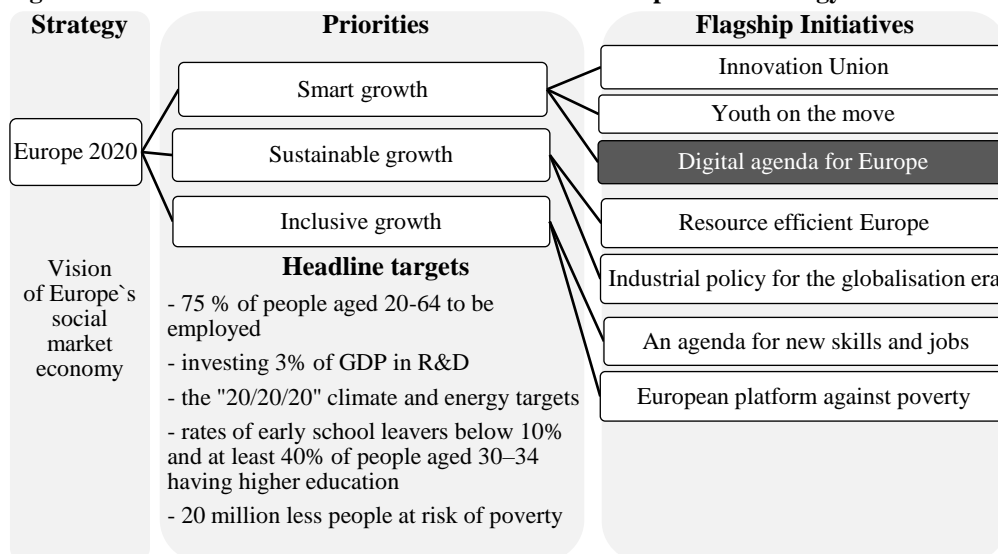

unemployment in the EU at this point was only of prime interest and concern (Commission of the European Communities, 1993, p. 9). The key role in overcoming this problem has been assigned then to development of the information society. The EU consistently included these issues in political agendas over the following years, seeking to create own socio-economic model, responsive to challenges posed by digital revolution and fitting ideas and values of the European social system, inter alia, determining equal opportunity for all citizens. However, continuous changes in rhetoric, unclear the very concept of information society and, primarily, its vague place in the Union's overall development strategy, the way of implementation and role in fulfillment the vision of European economy are criticized in analyses on the EU policy concerning development of information society from the beginning until the Lisbon Strategy (Feijóo, Gómez-Barroso and Karanitis, 2007; Servaes, 2003; Kaitatzi-Whitlock, 2000; Aulake, 1998). Therefore, the EU should have a strong incentive to change activity in this field and finally to develop a vision and strategy appropriate for the challenges of the Internet Age.

### ***3.1 Digital Economy in the Europe 2020 Strategy – a Holistic Approach***

The crucial difference between the Europe 2020 strategy and previous Lisbon strategy, which was aimed to make the Union 'the most competitive and dynamic knowledge-based economy in the world' (European Council, 2000) is the absence of the frame of reference (the benchmark) for the overall aim of current strategy. The priorities presented at the highest level in the Europe 2020 strategy relate first and foremost to the nature of economic growth (smart, sustainable, inclusive) and the areas of actions for achieving this (i.e. employment, innovation, climate and energy, education, poverty reduction), for which the levels of quantitative indicators were set out as headline targets to be accomplished in 2020 year (Figure 2). Taking the long term view, the objectives defined in this way are the backbone of any economic development, although it can be slightly different terminology used for them.

Actions under the key priorities of the Europe 2020 are addressed by seven equivalent so-called flagship initiatives. The role of ICTs and, in particular, the Internet is directly set out in the Digital Agenda (blacked out in Figure 2) listed in the Europe 2020 as third initiative to catalyse smart growth, understood in terms of strengthening knowledge and innovation as drivers of the EU's future growth. Seen in this light, it could be concluded that the exploitation of the potential of ICTs is not more important job for the EU than all other ones specified in remaining initiatives. Such a focus on the Internet (and more broadly ICTs) in development strategy could give rise to serious concerns in view of the challenges brought about by the digital revolution. This approach substantially differs from the essence of the Internet economy model.

However, if one looks carefully at the description of all other flagship initiatives, one notices that harnessing ICTs' potential is listed not only as one of many actions to achieve the priority of smart growth, but also, to some extent, to achieve the priority of sustainable growth. These issues are addressed in 'Resource efficient Europe' aimed to support the shift towards a resource efficient and low-carbon economy (European Commission, 2010b). It is also crucial that the competitiveness considerations are assigned to the sustainable growth priority and included in the initiative 'An industrial policy for the globalization era'. Moreover, there is also no clear hierarchy of targets and action, instead, their interrelatedness and representativeness are pointed out in this strategy (European Commission, 2010b, p. 9). The above, accompanied by very numerous and constantly varying targets which are communicated in many documents within each initiative, makes the overall strategy difficult to understand for an average European citizen.

**Figure 2: The Overall Structure and Content of the Europe 2020 Strategy**

Source: author's elaboration based on European Commission (2010b)

As it is seen in the case of the overall priorities of the Europe 2020 strategy, there is no focus on radical changes in modes of production, consumption, innovation and organization, and especially interactions among all stakeholders. There is no redefinition of roles of all economic and social actors. The preponderance of economic orientation (the goal of economic growth) and thus subordination of all other aims to this was also proved by the in-depth research (Verdegem and Fuchs, 2013).

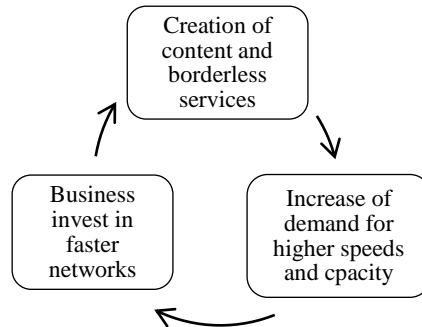

The introduction of the digital economy concept into the separate initiative (i.e. the Digital Agenda), but not at the level of primary priority in the Europe 2020 strategy means, in fact, that the digital economy is to be only a part of European economy rather than its equivalent. This is also acknowledged by separation the Internet sector from the whole economy and its treatment as distinct part (Hoorens, Elixmann, Cave et al.2012). All these reasons indicate a narrow, and therefore insufficient approach to the importance of Internet and related technologies for the economy and, as a result, a lack of clear adequate holistic vision of the European economy under challenging transformative circumstances. The EU is not intended to make profound changes towards the new socio-economic model (create the Internet economy par excellence), but seeks to improve or modernize its current model and attempts to adapt it to the new conditions. These efforts have not been successful so far.

### ***3.2 The Essence of Digital Economy under the Digital Agenda***

The Digital Agenda for Europe specifies how the EU, in fact, sees the potential of ICTs and, above all else, how intends to boost their use or maximize benefits for society and economy. According to this agenda, the activities for growth of the digital economy 'can be largely self reinforcing' and act as 'virtuous cycle' (European Commission, 2010a). Activating this mechanism can occur through providing attractive content and services at pan-European level (i.e. available in borderless Internet environment), thereby boosting demand for more advanced Internet infrastructure (higher speeds and capacity), and thus encourage the business

sector to invest in development of networks, and deployment of them in turn will open up new opportunities for innovations based on this networks (Figure 3).

**Figure 3: Virtuous Cycle of the EU Digital Economy**

Source: author's elaboration based on European Commission (2010a, pp. 4-5)

The adopted logic of the digital economy points out that the EU focus on the demand side of the economy, while people has been assigned a consumer role and their demand has to encourage the virtuous circle. This logic clearly shows how the concept of digital economy is different from the nature of the Internet economy model.

The very aim of the Digital Agenda is relatively difficult to identify, because in its introduction is stated that it is to reap economic and social benefits from digital single market, based on advanced Internet infrastructure and technical interoperability, but later on it is said that the objective is to maximize the social and economic potential of ICT, mostly the Internet. The consistence of aims described in this way will be ensured under just the assumption that completing the digital single market is the only basis for realizing benefits from the advances of Internet revolution. The resulting picture is that the EU has chosen the liberal approach towards digital transformation.

The justification for developing and implementing such a policy at the European level is existence of obstacles that distort or prevent from benefiting from digital single market. It has been found that digital (online) market is not implicitly included into internal market. The Digital Agenda shows seven types of impediments and presents measures to remove these limitations. The first three obstacles are mainly related to the regulatory frameworks. Their elimination, in fact, is the essence of completing the digital single market (as is the case for the internal market), the purpose of which is to ensure the free and safe flow and use of content and Internet services or services provided via the Internet. Two further obstacles relate to financial and technological issues, which include, in particular, inadequate investment in development of the Internet infrastructure and insufficient research and innovation efforts. The EU actions should be therefore focused on a provision of fast Internet access for all and generally raise expenditure on creation and commercialization of key technologies in the field of ICTs (such as the Future Internet). However, the financial instrument to pursue European policy objectives (i.e. Horizon 2020) is not designated for direct investment in infrastructure and research and development activity, but to private investment stimulation. The sixth obstacle concerns the human capital and indicates, first of all, a digital literacy deficit among citizen, while also points out shortage of appropriate IT specialists. The key measures adopted by the EU to resolve this problem are 'proposing digital literacy and competences as a priority

for the European Social Fund regulation (...) and developing tools to identify and recognise the competences of ICT practitioners and users (...)’ (European Commission, 2010a, p. 26). It is hard to find these actions as capable of addressing the key challenges that humans face meeting the new demands of ubiquitous digitisation. The last obstacle listed in the Digital Agenda concerns limited benefits from the use of ICTs and refers to weak use of all possibilities of these technologies for solving society problems (like climate change, an ageing population or integrating people with disabilities). However, it is questionable whether the latter obstacle should be considered in the same way as all other mentioned herein. Summing up, the actions under Digital Agenda are aimed at elimination of different kind of market distortions.

Moreover, the EU puts a strong emphasis on ensuring equal access to the Internet and possibilities to use it through acquiring appropriate e-skills (in particular, inclusion of persons disabled or socially excluded). This confirms that the principle of equality and convergence is deep-rooted in policies of the EU. There is no mention of educating and stimulating all citizens (Internet users) as producers and, in particular, as innovators (e.g. in response to social production model).

It can be inferred from the whole context of the Digital Agenda that the task of the European policy is to provide attractive content and services as well as to ensure conditions for frictionless functioning of virtuous cycle of digital economy in order to attain the benefits of the digital single market. Along with questions on rationale of the underlying assumptions for adopted vision of digital economy, it should be asked whether there was any coincidence in decision of use the virtuous cycle theory between the EU and the US when justifying the Internet’s openness (FCC, 2010). However, the debate on the virtuous cycle working in the US has been undertaken. Preliminary results of the empirical tests of the virtuous cycle theory application (Layton, 2014; Ford, 2017) show that:

- there is lack of positive effects (below expectations),
- there is no clear link between demand on Internet and investment in network infrastructure,
- it is questionable whether the virtuous cycle works in this area given that private firms traditionally didn’t invest in infrastructure.

Keeping above findings in mind, the key question is whether the virtuous cycle theory apply to the case in question. The more general one, what we should ask as the first is whether the genuine virtuous cycle need any intervention or regulation. So, the EU should thoroughly consider the rationales for development strategies set out at EU level. The actions taken forward under this strategy to date have not yielded expected results even in such crucial field as e-commerce, to which considerable importance is attached in the Digital Agenda and also in the new digital single market strategy launched in 2015 (European Commission, 2015). A large still unutilised potential of B2C e-commerce is confirmed, for example, by study carried out by Kunešová (2016).

### ***3.3 European Digital Economy Concept vs. New Internet Economy Model***

Drawing on submitted in the first section explanation of the Internet nature and the new socio-economic model interpretation, the Internet economy is characterised according to main criteria and attributes specifically worked out for this study (Table 1). In the same way the EU digital economy concept is stipulated in order to check their consistency. The basis for its characteristic is the above analysis of the holistic vision and essence of digital economy concept under the Europe 2020 strategy.

**Table 1: Checklist of the Consistency of EU Digital Economy Concept with the Internet Economy Model**

Criteria	Attributes	Internet economy model		EU digital economy concept	
		Yes	No	Yes	No
<b>Concept</b>	Radical new	x			x
	Upgraded		x	x	
	Holistic	x			x
	Fragmented		x	x	
<b>The role of state</b>	Elimination of market distortions only (passive)		x	x	
	Strong (active)	x			x
<b>State functions</b>	Regulator	x		x	
	Investor	x			x
	Propagator	x			x
	Controller	x		x	
	Market player	x			x

Source: author's elaboration

The differences between EU concept and reference model of the Internet economy are substantial. They are downright the opposite. Only two items are overlapped. The state in EU digital economy plays as regulator and controller, just like in the Internet economy model, but that is all.

#### 4. Conclusion

The digital revolution triggered the breakthroughs in virtually all areas of life, work, relations, and has led to the new socio-economic model (herein called the Internet economy model), where the role of human being in the economic processes and rules for value creation has been altered too. The literature review proved that the new environment imbued with ICTs requires also new institutions, new infrastructure, new behaviours, new organisational structures and the state has a proactive role to play in this digital transformation. The full utilisation of ICTs' potential requires profound and widespread changes towards the Internet economy model, and its creation needs holistic approach.

The EU also strives to take advantage of fast technological progress in the ICTs field and thus improve its competitiveness. This study of digital economy concept in the Europe 2020 strategy has found that:

- digital economy is treated as a certain part of European economy and actions in this field are not given higher priority than the all others set out in official policy documents,
- there is no focus on radical (disruptive) changes and digital economy does not constitute a new structure,
- digital economy creation is based on simple demand mechanisms (through inducing a highly dubious virtuous cycle) and competition stimulation, which are also expected to drive its economic growth - so it is liberal approach with minimum state involvement,

- digital economy, as well as the overall vision of Europe`s economy in Europe 2020 don`t sufficiently involve the whole society in process of value creation, and instead assign traditional role of consumers to citizens,
- digital economy concept is absolutely opposite to the Internet economy model, as such, it is not fit for the on-going digital revolution.

All of assumptions and objectives of digital economy concept and its place within the Europe 2020 strategy should be assessed negatively. The crucial issue is the lack of clear adequate holistic vision of the European economy under challenging transformative circumstances. Even if all measures and actions will be fully implemented, they are unable to meet the challenges and substantially change the EU`s position in the world economy.

The above conclusions are fundamental for individual EU Member States and should make them more aware that EU strategy provides for only continuation of the integration process by extending it for a new area created by the digital revolution (i.e. digital single market), instead of the establishment of completely new socio-economic structure able to meets the current challenges.

The study contains preliminary findings and further in-depth research should be undertaken, not only concerning the EU level but also individual economies and, in particular, proper model of economy functioning in the Internet age and its effective implementation. The role and functions of the state in ICTs-driven environment should also be carefully examined. It is desirable for future studies to take into account the experience of the leaders of digital transformation, as well as catching-up countries.

### **Abstract**

*Transparency is one of the major issues in all current EU trade negotiations. The lack of an adequate level of transparency has been often emphasized by many stakeholders, mainly by civil society organizations. On the other hand, premature or extensive public disclosure of the content of negotiations could risk the loss of mutual trust between negotiating partners and ultimately cause the failure of the negotiating process. The most visible transparency issues have emerged during TTIP negotiations and are still emerging in the process of Brexit. In this article, we try to identify parallels and differences in transparency issues within TTIP and Brexit negotiations. The identified similarities and differences within both processes demonstrate the evolution from total secrecy to a high level transparency in EU trade negotiations. In the case of TTIP, the demand for transparency was an undesirable element causing complications, in the case of Brexit, transparency was used as a negotiating tactics for achieving EU's goals.*

**Keywords:** Brexit, EU trade policy, transparency, TTIP

### **1. Introduction**

For a long time, international diplomacy has been considered to be the domain of a small number of elite diplomats and political representatives whose activities were rarely known to the general public. This is especially true for international trade negotiations which usually deal with highly technical matters concerning issues such as import quotas, tariffs and other types of trade barriers.

However, the situation began to change with the development of advanced economic integration projects in European area such as TTIP (Transatlantic Trade and Investment Partnership). This project was planned to have a much bigger impact on the EU economy than any other free trade agreement negotiated by the EU in its history. Therefore, the TTIP negotiations have drawn much more public attention than any other EU trade negotiations. The civil society organizations began to complain about a lack of available information in the negotiating process and the European Commission was tackled with the problem of insufficient transparency within trade negotiations.

The second negotiating process which has drawn significant public attention is that of Brexit. The withdrawal of the United Kingdom from the European Union has caused a lot of worries about the future arrangement of EU-UK relations among British and EU citizens, as well as

among businesses. No other EU trade negotiations have had so much public attention and demands for a higher level of transparency than TTIP and Brexit.

The aim of this paper is to identify the similarities and differences in transparency issues between the TTIP and Brexit processes. To do so, we performed a comparative analysis of both processes which include a content analysis of position papers and an analysis of the statements from involved actors. We also performed a comparison of the extent of the disclosure of important documents for the public and a comparison of the attitude of the stakeholders towards transparency in trade negotiations. We tried to analyse the evolution of the EU transparency policy in trade negotiations but we did not examine the transparency policy of the USA and UK.

## 2. The Role of Transparency in EU Trade Negotiations

A significant number of people believe that the problem with a lack of transparency in EU policies execution began together with the TTIP negotiations. However, there were certain transparency issues even before the entry of the Lisbon Treaty into force in 2009. The openness of the EU institutions was set and defined in the Regulation 1049/2001 which states: *Openness enables citizens to participate more closely in the decision-making process and guarantees that the administration enjoys greater legitimacy and is more effective and more accountable to the citizen in a democratic system. Openness contributes to strengthening the principles of democracy and respect for fundamental rights. (...) Wider access should be granted to documents in cases where the institutions are acting in their legislative capacity, including under delegated powers, while at the same time preserving the effectiveness of the institutions' decision-making process. Such documents should be made directly accessible to the greatest possible extent.(...) The right of access also applies to documents relating to the common foreign and security policy...* ('Regulation (EC) No. 1049/2001', 2001)

However, Regulation 1049/2001 in article 4.1 protects the secrecy of the documents whose disclosure would undermine the protection of the public interest regarding, among others, the dimension of international relations ('Regulation (EC) No. 1049/2001', 2001). The legal cases judged under Regulation 1049/2001 (such as *Verein für Konsumenteninformation v. European Commission*, 2005 or *Access Info Europe v. Council of the European Union*, 2011) were related to the internal dimension of the EU policies only and did not have any direct connection to the external relations of the EU.

After the entry of the Lisbon Treaty into force, there have been three lead cases from European Courts that deal with the transparency in the context of international agreements. The first one is the case *Sophie in 't Veld v. Council of the European Union*. It was brought before court by Sophie in 't Veld MEP who received partial access to the opinion of the Council Legal Service concerning the recommendation from the Commission to the Council to obtain the authorisation for the opening of negotiations for the so-called SWIFT agreement. This international agreement deals with the processing and transfer of Financial Messaging Data from the European Union to the United States for purposes of the Terrorist Finance Tracking Program. The second was *Sophie in 't Veld v. European Commission* which was brought before court because of the decision of the European Commission to deny access to several documents relating to the Anti-Counterfeiting Trade Agreement (ACTA) negotiations. The third one was the case *Leonard Besselink v. Council of the European Union* concerning the draft Decision of the Council on a negotiating mandate which should authorise the Commission to negotiate the EU Accession Agreement to the European Convention on Human Rights (Leino, 2017). In all these cases the judging courts accepted the objections of the applicants although not fully and in the second case, the General Court *proved to be sensitive to considerations relating to*

*the need to protect EU strategic objectives and the climate of negotiations* (Leino, 2017, p. 10).

The first case related to the lack of transparency in trade negotiations prior to TTIP was *Stichting Corporate Europe Observatory v European Commission*. Stichting Corporate Europe Observatory questioned the decision of the European Commission to refuse to grant full access to several documents relating to the negotiations between the European Union and India, aimed at concluding a free trade agreement. The General Court dismissed the claim of the applicant citing article 4.1 of the Regulation 1049/2001, specifically the third intent of the article – international relations. This judgement was also confirmed in appellate procedure by the Tenth Chamber of the Court (Eur-lex, 2015).

In trade negotiations there must be rational place for transparency and secrecy at the same time. Too much public disclosure can lead to the loss of mutual confidence between negotiating partners and leaves little manoeuvring space to reach the compromise (O'Reilly, 2017). Negotiating parties are usually not able to achieve their goals when their negotiating positions are known to their opponent. On the other hand, a bigger level of transparency in trade negotiations creates a predictable environment which helps businesses to set their trade and investment plans. It also reduces the pressure from the public to the governments and in some cases allows the negotiating process to be more relaxed and easier to handle.

The question 'How much is enough?' is going to be crucial for future trade negotiations. The point is to find the balance between the transparency and the secrecy. In the context of the EU trade negotiations, the Regulation 1049/2001 leaves significant space for different interpretation of its exceptions. The exceptions under the article 4.1 do not include the public interest test, which requires the institution to consider whether the access to the documents should be granted despite the fact that their disclosure would be likely to cause harm (Leino, 2017). Therefore, the EU institutions can relatively easily refuse to provide access to many documents which should eventually be accessible for the public. However, in the recent trade strategy of the European Commission 'Trade for all', transparency is one of the main pillars of the proclaimed future EU trade policy (European Commission, 2015).

### **3. Evolution of the Transparency Policy in TTIP Negotiations**

The process of the formation of TTIP started in 2013 and since its very beginning it was a valuable experience for the EU. Unprecedented public interest forced the European Commission to significantly improve and increase the transparency of the negotiations and to upgrade its communication strategy as well. At the start of the negotiations, there was no plan about making public any of the important negotiation documents related to the TTIP. Only the publication of the EU position papers was under consideration (Coremans, 2017). The insufficient amount of the information about the content of the negotiations fuelled a lot of groundless speculations which accused both sides of hiding something. Shortly after the start of the negotiations 80 organizations from the EU countries and the USA sent a letter to the then presidents B. Obama, H. Van Rompuy and J. M. Barroso, complaining about the lack of transparency in the negotiations (Gheyle and De Ville, 2017).

The European Commission responded to this demands by publishing a brief paper explaining the actors involved and the procedures of the negotiations (European Commission, 2014). DG Trade also published a limited number of negotiating texts on the internet (Coremans, 2017). But the pressure from the public was still substantial, therefore European Ombudsman Emily O'Reilly launched two investigations into the EU Council and the European Commission over a lack of transparency around TTIP. She called on both institutions to publish EU negotiating

directives and to ensure timely public access to the TTIP documents (Crisp, 2014). In October 2014, the TTIP negotiating mandate was published by the Council. It was the first negotiating mandate which was published even with the negotiations still ongoing. In November 2014, European Commission started to elaborate a targeted strategy aimed at demystifying the content discrepancies and increasing the number of available information sources. DG Trade increased the number of published EU position papers and started to publish lists of all unclassified TTIP documents shared with the EU Council and the European Parliament. An important element of the strategy was the personal participation of Commission's officials on seminars, conferences lectures and other meetings. Communication through social media was equally important. During 2015, DG Trade increased the rate of publishing of different factsheets and explanatory materials, which clarified even further the EU negotiating positions and approaches (Coremans, 2017). During this stage, we witnessed significant improvement not only in the quantitative aspect but in the qualitative as well. The European Commission tried to popularize the whole TTIP project and made considerable effort to provide access not only to the hardly intelligible papers for the general public but also to the explanatory materials. This change of policy raised questions of whether it could compromise the Commission's negotiating tactics on problematic issues. American negotiators did not publish many documents related to the TTIP negotiations, thus their negotiating position was better than the EU's position.

European Commission presumed that explaining the basics of the TTIP project would attract a lot of positive voices and eventually lead to a higher public support. The lurking scepticism about TTIP was attributed mainly to the lack of knowledge. The European Commission tried to sell the project to the public by using the narrative of 'jobs and growth' which eventually proved to be inefficient, partially because of not very favourable economic prognosis about the future impacts of TTIP. The most cited study at that time predicted only 0,5% increase to the EU GDP in 15 years time (CEPR, 2013). The 'jobs and growth' narrative eventually collapsed because it could not compete with the catchwords of the anti-TTIP campaigners like 'chlorine chickens' or 'shady courts overruling states'. The European Commission then tried to shift the narrative towards transparency. The increased number of documents available since October 2014 helped in part the European Commission to improve its image. However, this improvement was mainly between the academics who could follow the negotiations in detail without much delay. Lobbying groups welcomed the increased number of available documents as well. Nevertheless, the anti-TTIP campaigners rejected the changes of the EU as cosmetic moves (Van Ham, 2016).

The European Commission then tried to popularize the agreement as the 'strengthening of the EU's voice in the world,' but this slogan was inefficient too. After that, the Commission officials acknowledged the Commission's limits in credibility and its ability to sell the outcomes of the trade agreements to the general public and called for a more active involvement of the member states (Van Ham, 2016).

At the time of writing this paper, the TTIP negotiations are stopped but the transparency issues still remain. Achieved level of transparency in TTIP is being applied to other trade negotiations of the EU. However, there is still the question about adequate balance between transparency and secrecy. The civil society organizations, unlike businesses call for the implementation of maximalist interpretation of transparency which demands publication of every single document by rule. Furthermore, the civil society organizations ask for more opportunities for an equal and meaningful participation on the process. Businesses, on the other hand, are satisfied with the current level of transparency (Gheyle and De Ville, 2017). Finally, the overwhelming pressure from the public did have some positive impact on the content of the negotiations. The European Commission began to design a new court for the investor-state

dispute settlement and with the 'Trade for All' strategy it tries to conduct a more proactive transparency approach towards the public (Van Ham, 2016). The results of this effort did not materialize into the TTIP negotiations but it did materialize into other EU free trade agreements like CETA (Comprehensive Economic and Trade Agreement) with Canada.

#### 4. Transparency in Brexit Negotiations

The process of Brexit started in 2016 following the referendum from 23 June which made a decision on the United Kingdom's leaving of the European Union. The result of the referendum triggered a significant number of discussions about the future setting of all different kinds of mutual relations between both partners. The main issue within the Brexit process is the choice about the future form of the UK's flexible exogenous integration with the European Union. The flexible exogenous integration could function on a level of a common market, or a customs union level or on a free trade area level (Kosír, Slobodníková and Orlická, 2016).

Brexit is a rather unprecedented process for which it is difficult to find relevant parallels in the past. Never before has the European Union negotiated a withdrawal of one of its full and most prominent members. The United Kingdom has been a member of the EU's customs union for 45 years and a member of the European Single Market since its foundation in 1993 (Vavrek, Ardielli and Gonos, 2016). The economies of the EU and the UK are closely interconnected and their future partition will have a significant impact on a number of businesses and EU citizens. Therefore, the transparency of Brexit negotiations is an important issue worth of a deeper analysis.

Brexit negotiations began after the TTIP negotiations have been stopped. The European Commission officials tried to settle the principles of Brexit transparency very carefully, not to repeat the mistakes made in the TTIP negotiations. In contrast with previous trade negotiations, the European Commission has since the very beginning pledged to provide a very high level of transparency of the negotiations. *The Commission, as European Union negotiator, will ensure a maximum level of transparency during the whole negotiating process. Commission negotiating documents which are shared with EU Member States, the European Council, the European Parliament, the Council, national parliaments, and the United Kingdom will be released to the public* (European Commission, 2016). Published documents include agendas for negotiating rounds, EU position papers, non-papers and EU text proposals. In May 2017, the Council of the EU created a document called *Guiding principles for transparency in negotiations under Article 50 TEU* which includes 9 principles and a scheme explaining the disclosure possibilities for every kind of document used in Brexit negotiations (Council of the European Union, 2017). Furthermore, the European Commission disclosed the composition of the negotiating team and its negotiating mandate, too. Moreover, all meetings with lobbying groups or individuals must be registered in special Transparency Register which is available for the public (Kendrick and Sangiuolo, 2017).

EU's communication strategy on Brexit proved to be sufficiently efficient and successful so far. First, this level of transparency helped to demonstrate the unity and strength of the 27 remaining member states. The release of negotiating positions documents obliges the member states to stick with the common stance and not to pursue their own interests. This is in big contrast with UK's several ideas about the future direction of Brexit. Second, EU's Brexit transparency helps to reinforce the legitimacy of the EU in a democratic context. Such high level of openness reinforces the belief that the EU can conduct negotiations in the name of the nations of Europe. And until now, nobody really questioned the legitimacy of the European Commission during negotiations. Third, transparency helps the EU to control the public narrative about Brexit (Kendrick and Sangiuolo, 2017). This was major issue during TTIP

process when the EU was not able to affect the public debate significantly. Brexit is different. The EU officials publish their negotiating positions and suggestions sooner than their British counterparts. The timing helps to shape the media discussions and British representatives are usually obliged to act reactively to the EU ideas and thus can not be so effective in the defence of their own ideas.

In addition, such a level of transparency helps to eliminate almost entirely the risk of leaks. The experience from TTIP has showed the real danger posed by leaks of important documents. Unauthorized leaks undermine the credibility of the whole system, bring distrust between negotiation partners and create mistrust in the public. Even the cooperation within one negotiating team could be hard in the case of a leak. And finally, a high level of transparency helps to avoid the risks in the economy coming from financial markets and uncertainty (Kendrick and Sangiuolo, 2017).

However, there are still some objections petitioning for an even higher level of transparency from the EU as was demonstrated by the most recent letter from European Ombudsman Emily O'Reilly to Jean Claude Juncker, President of the European Commission. The European Ombudsman welcomed and appreciated the progress made in transparency of the Brexit process but before the start of phase 2 of negotiations, she encouraged the Commission to publish a joint progress report for every negotiation working group after every negotiation round. In addition, the Ombudsman suggested that the disclosure of meetings with interest representatives should include not only the chief negotiator but the entire task force as well. Furthermore, she expressed the wish that some specific parts of the future draft withdrawal agreement should be available for relevant stakeholders (European Ombudsman, 2018).

## **5. Conclusion**

Both processes, TTIP and Brexit demonstrated a wide range of transparency issues within EU trade negotiations. TTIP as well as Brexit, aim to secure a very ambitious trade agreement whose impact on the EU economy would be much greater than any other EU trade agreement. This is linked to greater public interest in the agenda of the negotiations which was never witnessed before in any EU trade negotiations. The main difference in both processes was the role, which transparency played during the negotiation period. Whereas in the case of TTIP, transparency was an undesirable element causing complications, in the case of Brexit, transparency was used as a negotiating tactics.

European Commission does not want to repeat the mistakes made during the TTIP negotiation process anymore. It learned the lesson and have used a different approach in case of Brexit. Process of Brexit started with a higher overall level of transparency than the TTIP in its final phase. And since its very beginning, it constantly maintained the demanded level of transparency. On the contrary, TTIP gradually increased its level of transparency but never satisfied all the public demands for transparency. Brexit's level of transparency helped to demonstrate the unity of the EU, increase the legitimacy, eliminate economic uncertainty and probably the most important of all – shape the public narrative about Brexit. During TTIP, the public narrative was shaped mainly by civil society organizations through social media and the European Commission was unable to influence it any significantly. In Brexit, the public narrative has been shaped by the EU institutions and then was taken by media and various stakeholders on social media.

These two examples demonstrate both ways of the application of transparency in trade negotiations. The improper way and the proper way. The TTIP process provided a valuable experience about complicated transparency issues for the first time in EU's history. And the

Brexit process demonstrates that even a high level of transparency can lead to desired negotiating outcomes and that a high level of transparency does not necessarily lead to the downgrade of the negotiating position.

### **Abstract**

*This paper is based on the characterization of the role of public administration regarding the problem solving of brownfields, especially in relation to its regeneration. The regeneration of abandoned and unused areas and buildings has been recognized as a key instrument in the sustainable land management. The conversion of brownfields is more effective and should be more acceptable to the public than the utilization of free developable land because of scarce and more expensive resource, especially in densely populated areas. That is why it is necessary to engage the public administration in cases in which the private sector is failing. This paper summarizes some of the selected tools of the public administration for problem solving of brownfields, and particularly defines the instruments of financial nature including the possibility of financing from EU funds (European Structural and Investment Funds and other) as well. Standard secondary data are used and combined with data from primary research carried out in relation to this subject in the city of Karviná (Moravian-Silesian Region, Czech Republic).*

**Keywords:** *brownfield, EU, public administration, public interest, public sector*

**JEL Classification:** *O18, R11, R51, R58*

### **1. Introduction**

The issue of brownfields has been recently coming into focus also due to the voluntary and forced activation of institutions of the public administration. It very often relies, beside other things, on the relevant tools for problem solving of the European Union. Brownfields are perceived in the context of the modern attitude and in relation to the economic development and current dynamic intensification of the life quality as a significant, yet specific element of the land development and spatial arrangement of the cultural-natural environment. Taking this into consideration, brownfields and the areas related to them should be in the interest of the representatives of the public and state administration, who by means of their activity and cooperation with other subjects are able to utilize the potential of brownfields to their maximum extent. The presented contribution thus focuses on defining the role of the public administration and the EU in relation to brownfields.

Brownfields refer to any land or premises which have previously been used or developed and are not currently fully in use (...) may be vacant, derelict or contaminated (...) therefore not necessarily available for immediate use without intervention (Alker et al., 2000). Brebbia et al. (2006, p. 40) define brownfield as: „any land or buildings, which have previously been used and which are now vacant or only used partly. They may be vacant, derelict or contaminated.

*That is why brownfields cannot be used immediately without any intervention.*“ Brownfields thus represent a significant environmental and social issue, and its solution is being reflected in the social-cultural development of the given level of the government (Greenberg et al., 2000; De Sousa, 2003; Thornton et al., 2007 or Williams and Dair, 2007). The formation of brownfields is usually generated by the economic-social factors stipulated in the branch-sectoral changes of industrial activities, always referring to the given area and the analysed object or phenomenon. The effects of brownfields with predominantly negative externalities are then manifested in the social sphere (social-pathologic phenomena or unemployment – Kunc et al., 2014 or Turečková et al., 2017a), economic (e.g. the price level of the properties in the brownfield surroundings is affected by them – Sun and Jones, 2013 and Turečková et al., 2017b), in the environmental sphere (in relation to the potential contamination and ecological pollution of built up areas and brownfields surroundings) or in urban or organization sphere (Frantál et al., 2013). All of the above mentioned is also reflected in the degree and the structure of the intervention of the institutions of public administration and self-government of problem solving relating to the brownfields existence. According to the study for brownfields localization (CzechInvest, 2008), there were 2 355 brownfields with the total area of 10 326 hectares in between 2005 and 2007 in the Czech Republic. Yet, the qualified estimates present us with the total number of 12 000 brownfields with an area of more than 38 000 hectares, while their number has been slightly decreasing since the 1990s (Rydvalová and Žižka, 2006). Thus we can claim that there is no such municipality in the Czech Republic without at least one brownfield in its cadastral area. Information on the assets of municipalities is presented primarily in the financial statements on the balance sheet (Kršková and Pakšiová, 2015). Based on the research carried out in the municipalities of the Moravian-Silesian Region, at least 80 % of their citizens are bothered by the existence of brownfields, and so it is in the public interest to solve the brownfield issue (Turečková et al., 2017a).

## **2. Problem Formulation and Methodology**

Brownfields are an issue for all municipalities and cities (further on, may the municipality and the city be perceived as a synonym), as they are their integral part. Besides their spatial connection, the brownfields are also connected to the municipalities functionally and visually. The derelict brownfields according to Kadeřábková and Piecha (2009) bring down the attractiveness of the municipality (it is then associated with a notion of degradation of the given area), which is then being transformed into an advantage to some extent. From the urbanistic point of view, the unutilized areas may be perceived as a restriction of disposable sources in a municipality with a direct link to the public budget. Reutilization of these abandoned localities improves the life quality of all actors due to a decrease in the criminality and socio-pathologic phenomena, an improvement in the local environment, an increase in land and area value, an increase in the perceived value of the neighbouring properties and an increase of the attractiveness for entrepreneurs (Hollander et al., 2010).

The intervention towards problem solving of brownfields must also respect the diverse localization of brownfields in different parts of the municipalities, in the so-called concentric zones (Park and Burgess, 1925). There is a consensus in the expert literature that brownfields represent barriers in the current structure of the cities, which then restrict the development of the area (Raco and Henderson, 2006). In the context of the brownfields regeneration, we can assume regarding the zonal model of the city that in the central parts – the most attractive parts of the cities, the reuse of brownfields will be directed towards the support of small business and housing. Such hypothesis reflects the contemporary reurbanization tendencies (Buzar et al., 2007). But beware – not always is such an intention successful, cf. the problem with dying of the city centres. The brownfields from the nearest surroundings of the city centre that were

incorporated into its hinterland during the dynamic development of the cities, have a rather variable utilization, e.g. for middle-sized business units or for building of civic amenities (Krzysztofik et al., 2012), while the vacant areas on the edge of the municipality are suitable for big industrial buildings or warehouses (Schindlerová, 2017). Provided that the preservation of the brownfields in a relatively original form is not desirable or possible (and there is not any suitable or more effective alternative), the possibility of the demolition of brownfields comes into consideration, or its demolition and decontamination of soil, alternatively its grassing and letting the unoccupied area without any concrete purpose (Johnson, Glover and Stewart, 2009 or De Sousa, 2000). Regarding the methodology, the paper is based on the literature retrieval relating to the researched problem. Regarding the objective of the paper, it is not possible to specifically define the role of the public administration or the EU institutions respectively, as the possible intervention from both of the subjects is to a certain extent fully individual and always unique with the respect to the given brownfield. Yet, general procedures of the public administration and the EU towards the problem solving of brownfields can be described (see the next chapter). In the contribution, the findings from the basic research done in 2016 based on the research questions on the perception of the citizens of Karviná of the derelict buildings in their immediate neighbourhood are mentioned. It is necessary to state that 655 respondents took part in the research questionnaire (more on the research Martinát and Turečková, 2016). The stated findings from the research will be relevant regarding the subject of the paper.

### **3. Problem Solving**

The area of brownfields and its solving falls within the competence of the government including the Parliament, specifically the Ministry of Environment and the Ministry of Regional Development. The issue also affects the Ministry of Industry and Trade, the Ministry of Environment and the Ministry of Culture, and the Ministry of Finance in regards to finances. It undoubtedly falls within the competence of other ministries and governmental agencies and institutions (CzechInvest, Centre for Regional Development, etc.). The European Union then helps to solve the problems with brownfields through its tools, especially by financing their regeneration from individual funds. The European Union unequivocally supports the investments in old buildings instead of supporting new buildings in the green field. Alongside, it recognizes the protection of the environment, preserving the contemporary urbanistic structure and interesting and valuable historical architecture. Regarding the financing of the regeneration and the redevelopment of the brownfields, the European Regional Development Fund and specific operational programmes such as Integrated Regional Operational Programme, Operational Programme Environment and Operational Programme Enterprise and Innovations for Competitiveness (more at <http://www.strukturalni-fondy.cz/>) are the most important ones. The European Union is dealing with the issue of brownfields on the local level indirectly (via financial programmes) and through individual public administration institutions.

The institutions at the level of the lower regional administration units, i.e. regions and municipalities, are closer to the problem solving of brownfields. The powers of regions are defined by a special regulation (Act no. 129/2000 Col.), according to which the region takes care of the general development of its area and the needs of its population. The region is administered by the regional authority, further bodies are the regional council, the regional council governor and the regional authority. The region is allowed to establish other bodies. Regarding brownfields, this issue can be also dealt with the boards and committees. The boards and committees can also be established by a municipality. The municipal authority is represented by the mayor, the vice mayor (vice mayors), the secretary of the municipal authority (if such a post is established) and employees of the municipality. The regional and

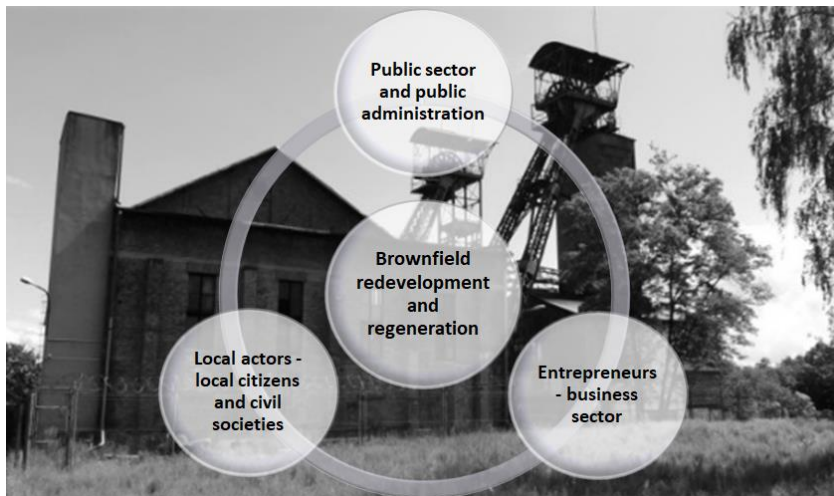

the municipal authority must be administered according to the principles of good governance of the public administration (Recommendation Rec (2007)7, 2008). The local administration regarding the brownfields plays an active role in the identification of brownfields, in reducing the effects of the brownfields, in the support of the owners and the consultancy, in the active support of the reutilization of brownfields, in the planning of the utilization of the brownfield sites and their neighbouring area , in the public promotion of projects dealing with the issue of brownfields, and in the prevention and protection against the development of new brownfields or protection against other related phenomena with negative social, competition or legal impacts (Růžicková and MacGregor Pelikánová, 2017). Table 1 clearly summarizes the individual actors involved in the sphere of brownfields.

**Table 1: Involved Actors in Problem Solving of Brownfields**

<b>involved actors on the personal level</b>	brownfields owners, consultants, off-governmental organizations, citizens and officials
<b>involved actors on the local level</b>	brownfields owners, local investors, local self-government, governmental bodies with local powers, technical, realty or legal consultants, financial institutions, the local population
<b>involved actors on the regional level</b>	brownfields owners, bodies of regional administration, regional financial institutions, regional development agencies, governmental bodies with local powers, regional investors and regional public
<b>involved actors on the national level</b>	government, parliament, affected state institutions and bodies, national regulatory bodies, national brownfields owners, national financial institutions and state investors
<b>involved actors on the global level and level of EU</b>	European Commission, European Parliament, global investors, global financial groups and international brownfields owners

**Figure 1: Stakeholders in Addressing the Issue of Brownfields**

Source: own elaboration (2018) based on Klusáček et al. (2011)

Note: The remains of the Gabriela Mine (2016), own elaboration

The above mentioned institutions of public administration involved in the problem solving of brownfields cooperate with the private sector and the citizens living in the concerned locality (see Figure 1). They always must be involved actors with a various level of direct influence and interest in solving the current unsuitable condition of the given brownfield, and persons who are indirectly involved with the regeneration and redevelopment.

**Table 2: Issues Connected With Brownfields, the Causes of the Intervention of the Public Administration**

<b>economic</b>	the loss of attractiveness for the investors and the visitors of the regions
<b>financial</b>	the decrease in the income to the public budget (fees), the ability to finance other public goods is threatened, the loss of the basis for tax calculation
<b>geographical</b>	deprivation of the neighbourhoods, unregulated urban sprawl
<b>ecological</b>	water pollution, soil contamination, buildings contamination
<b>social</b>	higher unemployment, higher criminality, the demand for social benefits

Source: Kadeřábková and Piecha (2009), own elaboration

Table 2 defines the basic issues that are connected with the brownfields and are the sources of interventions of the institutions of the public administration. A lot of effects of externalities are connected with these issues and are covered from the public budget (water pollution, increased air pollution, noise, soil contamination, concentration of poor population, or population threatened by the poverty, expansion of invasive species and the soil degradation, unregulated growth of cities and demands for the suitable technical infrastructure, etc.). The general problem of brownfields is their negative impact on the neighbouring properties, which then transforms into a further decline in the social status of the neighbouring community. As it is a local issue, the local administration is the key actor to deal with it. For Central Europe, the shortage of competences of public administration is typical of problem solving of brownfields, and even the well-informed and engaged local administration is obliged to cooperate with other (higher) levels of public administration: (1) government and legislative body must formulate and authorise inevitable proposed amendments to the relevant valid legal regulations, (2) it is necessary to prepare public programmes that solve the reuse of brownfields and reserve the financial resources for them, (3) the regions must pay attention to the sphere of brownfields when setting their priorities regarding the utilization of financial resources from the structural funds and also (4) the public administration must motivate the private owners to use effectively the abandoned localities, and the like.

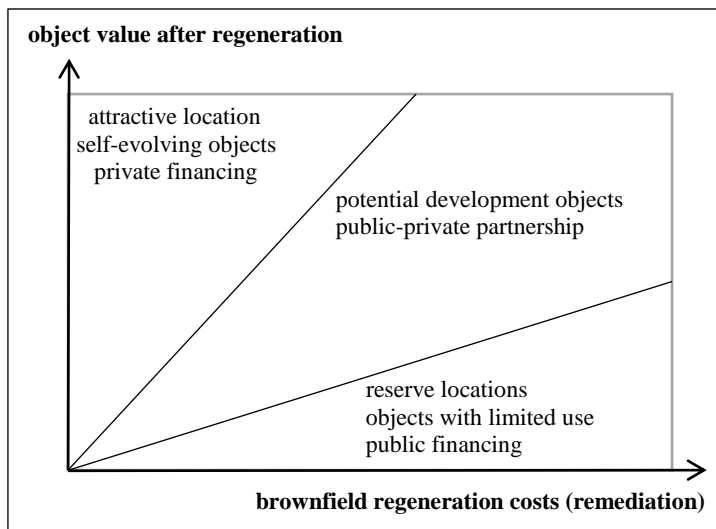

The definition of the role of the public sector may be also determined by the probability of the utilization of brownfield in the near future. The model ABC shows the level of the required intervention of the public administration in the form of public financial resources necessary for the further utilization of the brownfields offer (CABERNET, 2006), see the chart in Figure 2, where the vertical axis  $y$  represents the value of the land after the regeneration, and the horizontal axis  $x$  represents the costs for regeneration. According to this division, there are 3 groups of brownfields: (1) self-developing buildings in attractive localities, i.e. projects realized by a private sector. These are brownfields with a high developing potential that are situated in a good location and thus have a high chance that they will be looked after by the market itself. They are also typical of their reduced costs for the preparation and reconstruction when the public sector only sets the legislation frame without any need for public financial support. (2) potential buildings for the development (potential localities and areas for the development), i.e. the brownfields with a hidden developing potential, and with the local and

regional significance, yet with risks that the private sector refuses to accept. The projects on the elimination of brownfields are thus financed through the partnership of the public and private sector. It is then divided into three subgroups based on the size of the financial incentives:

- incentives of up to 20 % - it concerns the financing of the gap in the costs without which it would not be possible to implement the project. This investment is usually returned in some way, for example in the form of new job vacancies,
- incentives of 20 – 50 % - these projects are created primarily for public beneficial purposes such as e.g. protection of the environment or various social objectives,
- the last subgroup are the brownfields that are in such a bad condition that they not only damage the environment, but also the health, and they threaten the safety of the citizens. First, it is recommended that the full responsibility is taken by the guilty party, but if it fails, the public budget must cover the costs (securing the building or its demolition).

The last group (3) of this category are buildings without any developing potential with a restriction typical of its high costs for regeneration and at the same time a low value of the land after the regeneration. These brownfields are located in the areas where the supply highly exceeds the demand and no long-term commercial use is expected. The projects on solving such brownfields are fully financed from the public resources and with the sole activity of the institutions of the public sector.

**Figure 2: Types of Brownfields According to the Probability of Their Use (ABC Model Visualization)**

Source: Ferber et al. (2006), own elaboration

Regarding the focus of the contribution while following the basic research in the area of the statutory city of Karviná we can state that: the respondents generally prefer that the problem solving of brownfields is performed by the private sector and financed from the private sources (they perceive the connection with the taxes that they pay when financed from the public sources), but they insist on the intervention of the public administration with the long-term unresolved cases of brownfields in the city centre of Karviná. Such procedure is recommended rather with the vacant cultural and architecturally valuable buildings close to the centre. It is

a paradox that people demand the private solving of brownfields, yet they prefer to use them for public activities such as sports and relaxation purposes (sports ground, parks). When the city participates in the regeneration of the brownfields, the respondents want to use the buildings for housing. According to the results of the research, the institutions of the public administration should actively participate through their actions in the private solutions and intentions how to reuse the brownfield (e.g. whether it is appropriate to build a new shopping mall or a car park). The citizens expect from such an attitude that the originally vacant area gets regenerated and used and that the public interest will be maintained and the public attitude towards the individual locality will prevail over the solely private attitude. Last but not least, consultancy activities of the regional organizations of the public administration and public (state) agencies together with their direct drawing of financial sources from the EU structural funds are essential with the brownfields regeneration.

#### 4. Conclusion

The aim of this contribution was to outline some of the possibilities of the intervention of the public administration (using the EU tools) when solving the problems related to the existence of unused land, areas and buildings. Only an active local self-government and other public-law institutions will stand a chance to adequately use the limited tools and both financial and non-financial sources when regenerating and redeveloping the brownfields located in their own cadastral area. There is no doubt that the local self-government on the lowest local level is one of the key involved actor when revitalizing brownfields, and when properly motivated, it is able to find a solution or partake in the functional problem solving of brownfields in a short-term period.

### ***Abstract***

*Discussions on the process of European integration have been on the agenda since the day the European Union was established. The discussions of the Union whose first aim was to create an economic integration began to be seen at political and cultural levels as well. One of the issues affecting integration is considered 'Euroscepticism'. Many types of researches have been done within the scope of the Euroscepticism. It is also known that various researches have been carried out in countries on the determination of the Euroscepticism level of a society. However, it is seen that these studies generally remain at the descriptive level and there is no clarity about the fact that which factors are taken into consideration. The aim of this study is to show that the impact of Euroscepticism on European integration can also be measured by quantitative research methods and that the research factors can be extended to be done in all countries. Thus, a statistical analysis was carried out with the answers gathered from the International Relations Department students at Kocaeli University by survey method. It was aimed to generalize the questions of this study for all the countries which are probably as a subject of Euroscepticism.*

**Keywords:** *European integration, euroscepticism, euroscepticism factors*

**JEL Classification:** *F50, F53, N40, N44*

### **1. Introduction**

The European integration has been affected by many factors. Nowadays maybe the most prominent of them is the 'Euroscepticism' (Chuguryan, and Kucharčík, 2014, p. 280). The 'Euroscepticism', which has become increasingly important in the process of leaving the United Kingdom membership of the Union called Brexit, has become one of the most important factors affecting integration (Dorey, 2017, p. 27). The Euroscepticism, which has firstly began to be used in the UK since the 1980s, has intensified in the 1990s. There are some typologies of Euroscepticism which are used by experts. However, these studies generally seem to remain at a descriptive level. In order to fill this gap in the literature and to measure the level of the Euroscepticism in the countries, questions have been prepared and the answers to these questions have been aimed to determine the factors for the Euroscepticism in the countries. When studies on this area are examined, it is seen that there is not a study in which the effect of Euroscepticism on the European integration is investigated by quantitative research methods and the factors are determined in the framework of the debates about the future of the European Union (EU). With this regard, questions were asked about the measurement of the Euroscepticism and it was planned especially to ask the students of the International Relations Department of Kocaeli University by the survey method. It is thought

that the answers given by international relations students who have knowledge about the European Union will help to establish the factors that will arise in the effect of Euroscepticism on the European integration. Thus, the aim of the study is to show that the Euroscepticism can be measured by quantitative research methods and that the emerging factors can be broadened to include researches in all countries.

### **1.1 Literature Review**

When the international literature on Euroscepticism is examined, it is understood that the Euroscepticism has been a research subject since the 1980s (Matúš, 2016, p. 615). The term was first used in the 'The Times', published on November 11, 1985, during Margaret Thatcher's commentary on the European Economic Community. Studies after this date have attempted to explain how Euroscepticism is addressed in the literature and have assessed how it is on the agenda both theoretically and practically.

Before analyzing the literature, the term should be defined. One of the most accepted definitions of the Euroscepticism was suggested by Paul Taggart (1998, p. 365), according to him Euroscepticism is "the opposition and doubt to the process of European integration".

Euroscepticism can be understood as a discursive formation of arguments, which performed by political actors in rejecting the EU policies (Polk and Rovny 2017, p. 356). The nature of Euroscepticism is reactive. It means that Eurosceptic arguments are related not only to the European integration process itself but also to the justificatory discourse employed by political actors to legitimize this process. Eurosceptic people generally criticize the European Union for taking power away from the national government of member states and posing a threat to the sovereignty of the nations (Elsas, Hakhverdian, and Brug, 2016, p. 1182).

In the international literature, Euroscepticism was firstly used in a study which published by Paul Taggart. After that, Taggart again worked on the same subject in 1997 and 1998. The separation between soft and hard Euroscepticism has been made by Paul Taggart and Aleks Szczerbiak in 2002 (Taggart and Szczerbiak, 2002, p. 2-3). And most of the studies are generally based on the political parties' view of Europe (Veebel, 2017, p. 89).

Later, the typology which was suggested by Kopecky and Mudde has emerged. In addition to Taggart and Szczerbiak typology, they included the supporters of the European Union in the study of Euroscepticism (Kopecky and Mudde, 2002, p. 300). After that, it is seen that the works of Flood and Usherwood (2005, p. 6) has created a six type of factors that have affected the Euroscepticism. These factors are Maximalist, Reformist, Gradualist, Minimalist, Revisionist, and Rejectionist. In 2007, WeBels (2007, p. 288) has created a typology which has investigated the relation between European identity and Euroscepticism. In 2008, Sorensen (2008, p. 8) published an article which has showed 6 types of factors typology. According to her, these factors are national sovereignty, ideology, political performance, economic utility, effective pull, and principled opposition. And finally, Leconte (2010, p. 48) has made a typology which is based on a theoretical review of the Euroscepticism. The main point of all these studies is that all of them are generally analyzed the political parties' view to the EU and made some analysis within the context of the political environments of countries (Riedel, 2016, p. 808).

As it is seen in the literature review, there are studies to determine the dimensions of the Euroscepticism, but none of them seem to benefit from a statistical analysis. It is envisaged that this gap in the national and international literature will be filled in and it will be an example of future work on Euroscepticism. Therefore, it is thought that the most important original

value of this study is to present a model proposal which can be applied in every country by suggesting a new scientific analysis in the field of Euroscepticism.

The Euroscepticism is one of the most important threats to the European integration process. While the enlargement of the EU has occurred, the integration capacity has begun to be discussed by all of the member states and the EU citizens (Schimmelfennig 2008, p. 919). Developing a coherent policy can be more difficult with 28 members than with 15 members. And it is possible that the membership of the new European countries can bring new policy perspectives to the EU because of their different cultures, geographic locations and historical experiences (Sjursen 2002, p. 499). These new perspectives can be criticized by the EU citizens and also by some political parties. Thus the relation between the level of Euroscepticism and the European integration is more and more important during the time of economic, political and social crisis which the EU has faced.

## **2. Problem Formulation**

Within the scope of the study, firstly the terms of Euroscepticism and European integration and the relation between these terms have been given briefly. The survey questions have been selected in the light of current developments and the literature review. The survey has been applied to Kocaeli University International Relations Department student. It was decided that the scope of the responders should be limited to the International Relations students because these students are more interested in the EU policies and more relevant to current international issues than the students of other departments. Also, compared to other faculties and departments in the University, International Relations has been influenced by the inclusion of higher levels of involvement in European-related fields of study in future plans of students.

The survey method which is the closest to the social sciences was selected as the quantitative research methods. The questions in this survey have been tried to be kept at the general level in order to ensure the applicability in all countries. There are five determined dimensions which are aimed to measure the level of Euroscepticism and the results of the survey will be determined whether it is successful to find the determined dimensions or not. After determining the factors, the effects of these factors on the European Integration will be analyzed. At this process, the Likert scale was used: (1) Absolutely Participating, (2) Participating, (3) Undecided, (4) Not Participating, (5) Absolutely Not Participating. Moreover some closed-ended questions about the European perception of respondents were added, so it is aimed to understand the interaction between the dimensions of the Euroscepticism and the European integration. Finally, with socio-demographic variables, questions were also asked regarding gender, age, marital status, education, place of residence, and income status of the family.

### **2.1 Model and Data**

This study tries to prove that Euroscepticism can be separated into the factors and the survey method can be used in determining these factors. Surveys can determine the general tendency in a group of people, but when statistical analyzes are used, it is known that the results can be applied and improved on other groups as well. Thus this study was carried out in order to understand whether the result of the questions prepared in the light of literature analysis will help to evaluate the factors of Euroscepticism or not. It has been shown that the factors for explaining the Euroscepticism in the literature can also be demonstrated by statistical analysis.

Questionnaires were asked to undergraduate students of Kocaeli University International Relations Department. The responses to the questionnaire were collected and data were entered into the SPSS program. As a result of the survey application, 412 students were reached. Five important factors were determined by literature review and it was tested whether these factors could come out with the survey study. These factors can be listed as economic, political, cultural, social and democratic.

In the light of the demographic questions directed to the respondents; 50.2% of the participants are female and 49.8% are male. Participants' ages range from 18 to 25, with a maximum age of 21. 98% of participants are single. The class distribution in universities is equal. Thirty-five percent of the respondents reside with their family, while 27% of them reside in a government dorm. Finally, it appears that the income status of the family of 65% of the participants is below 5000 Turkish liras per month.

The answers were subjected to reliability analysis before the survey results were analyzed. According to the Cronbach's Alpha reliability analysis in the SPSS program, the survey was found to be reliable at a rate of 0.771.

In order to understand the level of Euroscepticism, 32 questions were asked of the respondents. These questions were subjected to factor analysis and the single-question factors were removed during the analysis. As a result, it is seen that the 5 important factors that are thought to occur in the context of the literature review are also the result of statistical analysis. Factor analysis results, questions that are evaluated in the formation of factors and components in the factor analysis can be seen in the following tables.

**Table 1: Economic Factors that Affect the Euroscepticism**

<b>Economic Factors</b>	<b>Component</b>
The standart of life will increase.	.687
Economic growth will increase.	.749
Job opportunities will increase	.743
National currency can be ended.	-.502
There will be free movement of goods within Europe.	.685
Standart of living will be worsen.	-.455
Economy will be worsen.	-.674

**Table 2: Cultural Factors that Affect the Euroscepticism**

<b>Cultural Factors</b>	<b>Component</b>
There will be cultural degradation.	.660
Moral characteristics of nation will be negatively affected.	.485
There will be more respect for other religions.	.323
It will be easier to learn foreign languages.	.500
The official language structure will be distorted.	.557
Historical values will be lost.	.697
National identity will be assimilated.	.774

**Table 3: Political Factors that Affect the Euroscepticism**

<b>Political Factors</b>	<b>Component</b>
Nationalism will rise.	.652
There will be more interferation to domestic politics.	.393
It contributes to the improvement of public order.	.543
There will be a political trust environment.	-.232

**Table 4: Democratic Factors that Affect the Euroscepticism**

<b>Democratic Factors</b>	<b>Component</b>
Respect for human rights will be more important	-.398
There will be more gender equality.	-.342

**Table 5: Social Factors that Affect the Euroscepticism**

<b>Social Factors</b>	<b>Component</b>
There will be more social rights.	.092
There will be more educational opportunities.	-.186
Working conditions will be improved.	.070

As it can be seen in the tables, the level of Euroscepticism can be analyzed in terms of economic, cultural, political, democratic and social factors. These factors which are considered as dimensions of Euroscepticism in the literature can also be found in the result of statistical analysis. This will allow the study to be applied to all groups, parties, and countries in order to create a model for understanding the level of Euroscepticism.

Once the factors are identified, it is necessary to determine the extent to which these factors have influenced European integration. For this reason, the mutual analysis of the questions about general European integration, which is asked after the questions about Euroscepticism, is important. It will be possible to test hypotheses with the aid of the ANOVA test and to understand the effects of the factors of Euroscepticism on the European integration.

The hypotheses can be varied, but within the scope of this study, it is aimed to reveal the extent to which the general view of the EU is affected by these factors. For this reason, the hypotheses are as follows:

H<sub>0</sub>: Participants' perceptions of (economic, cultural, political, democratic and social) issues do not differ significantly from their views on the EU.

H<sub>1</sub>: Participants' perceptions of (economic, cultural, political, democratic and social) issues do differ significantly from their views on the EU.

These hypotheses were subjected to the ANOVA test separately for each factor. If sig. value is above 0.05, it is known that the H<sub>0</sub> hypothesis is accepted and if sig. value is below 0.05, the H<sub>0</sub> hypothesis is rejected. According to this fact, the analyses have been made. H<sub>0</sub> hypothesis is rejected in the context of economic factor and it can be stated that there is a significant difference between the groups. Therefore, participants who are negative to the EU are found to have higher perceptions of economic issues. In the context of the cultural factor, the H<sub>0</sub> hypothesis is accepted, and there is no significant difference between the groups. In the context

of the political factor, the  $H_0$  hypothesis is rejected and it is evaluated that there is a significant difference between the groups. Regarding which answer is meaningfully differentiated, it is understood that the participants who are negative towards the EU have higher perceptions of political issues. In the context of the democratic factor, the  $H_0$  hypothesis is rejected and it can be interpreted that the participants with a negative opinion about the EU have higher democratic perceptions. Finally, it is seen that the social hypothesis is rejected in the context of the social factor, and it can be stated that the participants who are negative towards the EU have higher perceptions of social issues.

### 3. Conclusion

The aim of this study is to solve the problems faced in the European integration process by analyzing all of the questions that are discussed in all studies together, so that the dimensions of the Euroscepticism are revealed. This study aims to show the effect of Euroscepticism on the European integration, by using statistical methods. Hence, it will be possible to create a statistical prototype for studies which will be done after that. Showing the applicability of this prototype is the most important purpose of this study. This is because the Euroscepticism should not be considered in the sense of opposing the whole of European integration. The Euroscepticism stems from the fact that countries, groups, political parties, or even, if delimited individuals are willing to stay away from integrating because they can lose their superiority in areas where they think they are advantageous. In this respect, it is thought that the presence of the dimensions of Euroscepticism by assessing the Euroscepticism within the framework of certain questions and subjecting the questions to factor analysis is considered to be very useful for understanding the effect of Euroscepticism on European integration. The most important outputs to be achieved as a result of this study are; to analyze the Euroscepticism in all countries statistically with the created dimensions of the Euroscepticism and to see the obstacles in front of an effective European integration more clearly.

When we analyze the results of this study, it tried to understand whether the International Relations students of Kocaeli University are Eurosceptic about the membership of the EU or not. As a result, it can be seen that the students find the cultural issues useful for Turkey's EU membership, but they are Eurosceptic on economic, political, social and democratic issues. At these points, there can be more delicate balances between Turkey and the EU, so if an effective European integration is aimed at, it is necessary to carry out the regulatory works for these four (economic, political, social and democratic) factors.

### **Abstract**

*Research and development and innovation are key policy components of the Europe 2020 strategy. These elements should play a key role in securing the competitiveness of the whole EU in the future while maintaining internal territorial cohesion. By contrast the above mentioned activities naturally tend to the spatial clustering. In this paper the authors elaborate on the situation of the Czech Republic and its regions in relation to the Europe 2020 strategy target on Research and Development. The objective of the paper is to analyse selected research and development aspects from the quantitative and qualitative perspectives. The quantitative part reflects flows of the inputs related to the R&D activities. The qualitative part is extracted from a survey conducted by the Technology Agency of the Czech Republic in 2014. Survey is focused on the cooperation among relevant actors of the R&D collaboration. The outcomes show that the greatest barriers of cooperation among relevant actors are represented by bureaucratic burdens.*

**Keywords:** Europe 2020 strategy, knowledge flows, regional development, Research and development, spillovers

**JEL Classification:** I23, O39, R00, R11

### **1. Introduction**

A smart economic growth based on knowledge and innovation, while fostering social and territorial cohesion, represent two interlinked areas listed among the key priorities of the Europe 2020 Strategy. The Strategy execution is supported by seven flagship initiatives launched by the European Commission in order to support the progress towards all the Strategy goals. The “Innovation union” flagship initiative aims to improve the conditions for research and innovation. The main weaknesses to tackle within this initiative are the underinvestment into Research and Development (compared to USA or Japan) and unsatisfactory framework conditions for the Research and Development (R&D) itself, as well as for turning the R&D outcomes into the value for the private sector. The cooperation between the scientific and business world shall be improved and the barriers for bringing innovations to the market shall be removed. In parallel to the Innovation union flagship initiative, also a Regional Policy was launched, in order to “promote innovation in all regions, while ensuring complementarity between EU, national and regional support for innovation, R&D, entrepreneurship and ICT” (European Commission, 2010c, p. 2). A significant diversity is perceived in the R&D and innovation performance across the EU regions. It is equally important to support excellence of the advanced regions, as to mobilise the full innovation potential of the lagging ones, in order to unlock the growth potential of the European Union as a whole (European Commission, 2010a, 2010b, 2010c).

Research and development activities, innovation, knowledge creation and learning can be regarded as critical when it comes to ensuring a competitive edge of firms, as well as regions and entire states. The spatial aspects play an important role in here, not only in the area of innovation and knowledge creation, but also in their diffusion (Jaffe, Trajtenberg, Henderson 1993; Audretsh and Feldman, 1996). Obviously the geographical proximity itself is not the only pre-requisite. Next to the geographical one there are other forms of proximity playing a key role here, such as cognitive, organisational, social or institutional one. All these proximity forms are mutually complementing each other, but can be also substituting each other (Malecki, 1980; Malmberg and Maskell, 2002; Storper and Venables, 2004; Boschma, 2005). Boschma (2005, p.62) states that: “What unites the different dimensions of proximity is that they reduce uncertainty and solve the problem of coordination, and, thus, facilitate interactive learning and innovation”.

An important phenomenon to take into consideration when looking at regional diversity and uneven regional development are the externalities of regional economies, i.e. the fact that they interact with each other. The externalities are not only including knowledge spillovers, but also the effects of specialized labour and output market and the related accumulation of production factors (Lopez-Bazo, et al., 2004; Paci and Marrocu, 2013; Klimova and Zitek, 2016). The basis for the convergence are the industrial clusters, enabled by the knowledge spillovers and the inter-firm demand-supply networks (Parent and LeSage, 2012; Harris, 2011). Hence the “innovation is increasingly understood as an open system where different actors collaborate and interact” (European Commission, 2010c, p. 2). The level of collaboration and interaction influences essentially the impact of the research and development externalities (Fu, 2015).

In the context of the above mentioned, the authors of this paper focus on one hand on a spatial inequality, or more precisely a geographical concentration of R&D activities, and on the other hand on qualitative aspects of the cooperation between the private and public sector.

## 2. Problem Formulation, Data and Methodology

The objective of the paper is to analyse selected R&D aspects in the Czech Republic from the quantitative and qualitative perspectives. The quantitative part reflects flows of inputs related to the R&D activities. The qualitative part is extracted from a survey conducted by the Technology Agency of the Czech Republic (TACR) in 2014. Survey is focused on the cooperation among relevant actors of the R&D collaboration.

For the quantitative analysis the data available from the Czech Statistical Office are utilized. The row data are in a form of time series of R&D workplaces, employees and expenditures on NUTS III level. Each of the variables is further split into sectors: entrepreneurial, governmental, universities. The years included in the elaboration are 2005-2015. The input flows related to R&D are investigated from the spatial perspective based on the calculated Theil index. Its values are compared on bi-annual bases. The Theil index shall have values from the interval  $0 \leq T \leq \ln k$ , where the maximum value is reached, if the monitored indicator is concentrated into one spatial entity only. Due to uneven sizes of the NUTS III regions, the weighted version of the Theil index is applied according to the formula:

$$T_v = \sum_{i=1}^k \frac{n_i}{n} \frac{y_i}{y} \ln \frac{y_i}{y} . \quad (1)$$

The weighting parameter is the mid-period population, since the population is perceived as the primary agent of the economic activities. The population size reflects approximately the size and the socio-economic potential of a territory. In the formula (1)  $k$  stands for the number of

regions,  $y_i$  for individual values of the variable in question and  $y$  for the mean of this variable. The number of regions used in this case is 13, since out of the 14 NUTS III regions, Praha and the Central Bohemian Region are aggregated into one due to their natural geographical characteristics. (Theil, 1965; Novotny, Nosek and Jelinek, 2014; Suchacek et al., 2017).

The data for the qualitative assessment consist of TACR clients opinions collected within two questions of the survey realized in 2014: the respondents were asked to choose motives that lead to their cooperation with the research institutions and also to select the most important barriers observed within such cooperation. The sample includes answers from 447 respondents, out of 5150 emails sent out (9% response rate of the questionnaire). The questions concerning motives and barriers are constructed as multi-selection questions; a set of motives and barriers is presented to the respondents to choose as many as applicable.

The qualitative analysis purpose is to group the motives/barriers items based on their relevance similarity. Given the qualitative data type, the analysis is utilizing the concept of the “grouping based on the confidence intervals” (Friedrich et al., 2018, p. 90-93), in this particular case the interval estimates of the population proportion. They are constructed around the point estimate of the population proportion (i.e. the sample proportion) according to the formula (2) (Hendl, 2006), where  $p$  represents the sample proportion,  $n$  the sample size and  $z$  the z-score for the particular significance level:

$$p \pm z_{1-\alpha/2} \sqrt{\frac{p(1-p)}{n}} . \quad (2)$$

In the second part of the qualitative analysis all items are sorted in the decreasing order based on the sample proportion. And finally the overlaps of population proportion confidence intervals are evaluated, in order to identify groups of motives and barriers that are significantly different from the rest of the items.

### 3. Problem Solution

The outcomes of the quantitative and qualitative analysis are described in the following subchapters.

#### 3.1 Quantitative Analysis

The development of the geographical distribution of the R&D inputs flows in the Czech Republic is captured in the Table 1. The attention is paid to the distribution of the R&D workplaces, employees (in full time equivalents) and total R&D expenditures. Also the differences between the private sphere, represented by the entrepreneurial sector, and the public sphere, represented by the governmental sector, and universities are followed.

Generally it can be stated that the geographical inequalities are decreasing in time. This trend is obvious in all tracked areas and in all sectors. However when comparing the figures of the first and last years, it can be concluded that the de-concentration trend is very modest; the differences between Theil index values are not bigger than 0.1. The only exception can be observed in the R&D expenditures in the university sector, where the Theil index value decreased between the first and last year by 0.111.

The least geographically concentrated category is the number of R&D workplaces. This statement is valid for all tracked sectors and during the whole tracked time period. Also it is

evident that the governmental R&D workplaces are much more concentrated in comparison to university workplaces and private workplaces.

The geographical distribution of R&D employees is characterized by a higher concentration than the workplaces in all sectors and during the whole time period. The comparison of employee concentration between sectors results in a similar pattern as with the workplaces.

The R&D expenditures are among the tracked basic R&D inputs the most geographically concentrated. This can be observed during the full time period and across sectors. The only exception are university R&D expenditures in years 2011 and 2013, where the concentration is lower than the concentration of university employees.

**Table 1: Theil Index for R&D Workplaces, Employees and Expenditures per Sector/Time**

	2005	2007	2009	2011	2013	2015
Workplaces						
<b>Entrepreneurial</b>	0.380	0.379	0.369	0.338	0.344	0.318
<b>Governmental</b>	0.789	0.740	0.718	0.713	0.723	0.722
<b>Universities</b>	0.425	0.456	0.450	0.421	0.437	0.397
Employees						
<b>Entrepreneurial</b>	0.527	0.544	0.478	0.465	0.470	0.450
<b>Governmental</b>	1.158	1.146	1.129	1.115	1.093	1.088
<b>Universities</b>	0.555	0.611	0.599	0.555	0.556	0.522
Expenditures						
<b>Entrepreneurial</b>	0.573	0.650	0.525	0.472	0.546	0.519
<b>Governmental</b>	1.187	1.212	1.162	1.153	1.114	1.180
<b>Universities</b>	0.669	0.626	0.641	0.526	0.492	0.558

Source: authors' calculation

Despite the fact that the geographical concentration of basic R&D inputs is decreasing in time, a significant dominance of certain regions in the Czech Republic can be noted. In all studied aspects and during the whole tracked time especially two regions were standing out: the Central Region, including Prague, the Capital City, together with the Central Bohemian Region; and the South Moravian Region. A selection of the absolute and relative numbers of the year 2005 (and in brackets also 2015) is presented in the following paragraphs.

When it comes to the R&D workplaces in the Czech Republic there were in total 1 956 (2 811) workplaces; out of which 1 588 (2 387) in the private sector, 209 (196) in the governmental sector and 159 (228) at the universities. In the Central Region were located 34% (29%) of private R&D workplaces; 57% (55%) of governmental ones and 35% (33%) of the university workplaces. In the South Moravian Region, there were placed 15% (17%) of all private R&D workplaces, 15% (14%) of the governmental and 16% (18%) of the university ones.

Concerning the R&D staff, there were altogether 43 141 (66 186) R&D employees in the Czech Republic, out of which 21 116 (36 365) in the private sector, 11 054 (12 953) in the governmental sector and 10 972 (16 868) at the universities. In Prague and its surroundings there were employed 42% (36%) of all private sector R&D employees, 81% (79%) of employees in the governmental sector and 41% (37%) of university employees. In the South Moravian Region there were employed 12% (20%) of the private sector R&D employees, 12% (13%) of the governmental sector and 20% (24%) of the university employees.

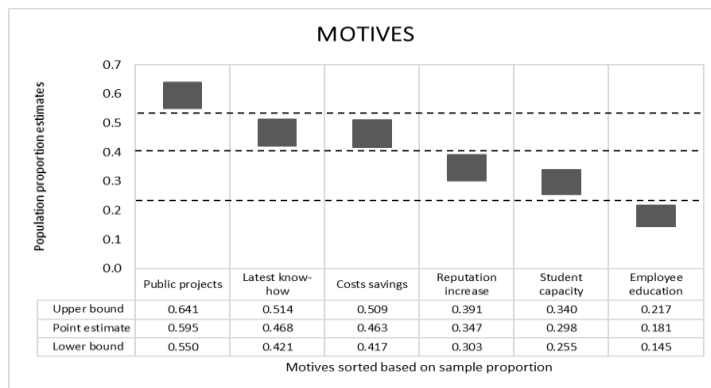

The total R&D expenditures (figures in millions CZK) on the country level were 37 952 (88 321), out of which 22 186 (48 148) were spent in the private sector, 8 686 (18 091) in the governmental one and 7 080 (22 083) at the universities. The R&D expenditures in the Central Region represented 45% (41%) of the private sector sources, 82% (86%) of the governmental expenditures and 47% (35%) of all university R&D expenditures. The shares of the South Moravian Region were 10% (18%) of the private sector R&D expenditures, 11% (9%) of the governmental ones and 21% (32%) of the university R&D expenditures.

Based on the presented figures the given regions can be marked as R&D centres of the Czech Republic. In some of the aspects their dominant position is even being strengthened. However, it can be stated, that in most of the tracked aspects the position of the Central Region is being diluted. Contrariwise the position of the South Moravian Region in the R&D area is reinforced. Generally we can conclude that despite the significant increase of the R&D expenditures and employee numbers, as well as R&D infrastructure strengthening efforts, the spatial distribution of the R&D activities in the Czech Republic stays relatively strongly concentrated.

### 3.2 Qualitative Analysis

The qualitative part of this paper is focused on one of the key areas within R&D and that is collaboration among the main parties. Firstly all motives (and equally also barriers) were sorted based on their sample proportion in a descending order, i.e. the items raised by the most respondents are considered as the most important. Then for each item among the motives (and also barriers) the 95% confidence intervals for population proportions were calculated and based on them all motives (and barriers) consequently grouped. The grouping is built on the fact that items with overlapping confidence intervals are not statistically distinguishable on the given significance level, hence the groups borders are between intervals, where the lower bound of an interval is higher than the upper bound of the following one.

**Figure 1: Motives - Confidence Intervals for Population Proportion and Grouping**

Source: authors' elaboration

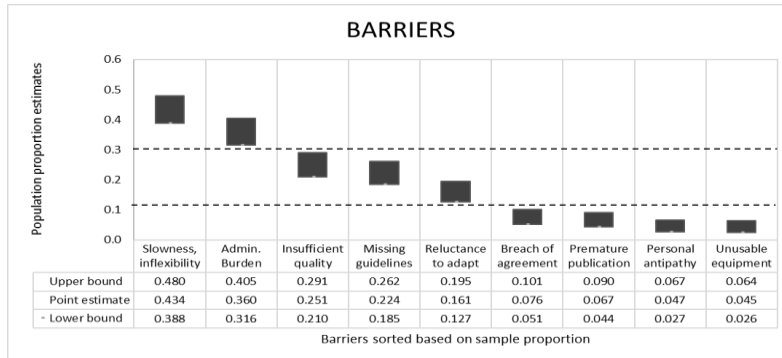

The outcome of the motives analysis is captured in Figure 1, displaying the relevance of the private sector motives standing behind their R&D cooperation with the universities and research institutions. As shown in Figure 1 the six original motives are, based on the population proportion interval estimates, merged into four categories:

- a. Public projects – the most important aspect, highlighted by almost 60% of respondents as the motive leading to the cooperation with research institutions was “gaining a competitive advantage through projects funded from public sources (research)”.

- b. Latest know-how, Cost savings – the second category of motives includes “easier access to the latest know-how/technologies”, but also “saving costs for research”, hence both of the items are pointing the benefits of the external R&D collaboration in comparison with company internal R&D.
- c. Reputation increase, Student capacity – the third group includes items “enhancing the reputation of the company” and “utilization of student capacity especially with regard to access to a qualified labour force”.
- d. Employee education – the least important motive is “activation of further education of employees”. The benefit of increasing the competence level of employees is perceived as minor compared to the rest of the motives presented.

Generally it can be concluded that primary motives encouraging the private sector to the cooperation with R&D organizations are related to the competitive edge gaining and market position strengthening. The competitive edge shall be gained in particular via external financial sources, internal costs reduction and latest know-how and technologies access and adaption. It is somewhat surprising that the motive of employee education is left behind, especially in the context with the fact that in the R&D field the tacit knowledge plays a key role.

**Figure 2: Barriers - Confidence Intervals for Population Proportion and Grouping**

Source: authors’ elaboration

The barriers elaboration, visualized in Figure 2, is built on the barriers relevancy as stated by private sector respondents, based on their experience within the cooperation with the R&D institutions. The evaluation of the population proportion interval estimates, calculated for each of the nine original barriers, lead to the grouping into three categories:

- a. Slowness and Inflexibility, Administrative burden – according to the respondent’s opinion the most important barriers, hindering the cooperation, are “slowness and inflexibility of the university system” and “high administrative burden on the company”.
- b. Insufficient quality, Missing guidelines, Reluctance to adapt – in the second category is included the barrier of “insufficient quality of research / services of the university/ RO; together with the “absence of clearly defined methodologies and guidelines for research collaboration”, as well as the “reluctance of university / RO to modify the research carried out based on relevant information”.
- c. Breach of agreement, Premature publication, Personal antipathy, Unusable equipment – among the least frequently perceived barriers are the last four items: the “failure of university / RO to comply with agreements in research collaboration”, the “premature publication of the results of joint research by university / RO”, the “personal antipathy” and the “unusable instrumentation of the university / RO”.

Obviously the most important barriers, limiting the cooperation from the private sector point of view, are of the institutional character. In the first place it is the administrative heaviness of the entire process and inflexibility within the system. Another limiting aspect is the absence of clearly defined working practices. Also the quality of R&D services is not satisfactory. On the other side the technical infrastructure challenges and personal conflicts are perceived as the least occurring.

#### 4. Conclusion

In the analysed time period, starting in year 2005, the R&D activities in the Czech Republic are clearly growing. The development of the R&D infrastructure is accompanied by the capacity increase of the human resources involved in the R&D area. In parallel also the R&D expenditures are raised. This trend is valid for the private, as well as the public sphere, but does not lead to a major decrease in spatial inequalities in the Czech Republic. Although the geographical concentration of R&D basic inputs flows is slightly lowered, two main R&D locations in the Czech Republic are identified. Prague together with its surroundings and the South Moravian region are dominating in the long term in all tracked areas and sectors. While the position of the Central Region is relatively diminishing, the dynamic progress of the South Moravian region is very evident.

The qualitative part of the paper was focused on the key area of the cooperation between the businesses and research organizations. The motives leading to the cooperation from the private sector point of view were analysed. The most important motive identified is the competitive advantage coming through the public sources projects. Also the possibility to access and adapt the latest know-how and the reduction of own R&D costs are perceived as relevant motives. Surprisingly the employee competence development related to the research projects was a motive with the lowest importance. The attention has been paid also to the barriers limiting the cooperation from the firms' point of view. Three main categories of barriers were identified. The most significant is the category of the institutional barriers, including the slowness and inflexibility of the R&D system, together with the heavy administrative burden. The second category is related to the working practices within the cooperation and the quality of research services. The least problematic seems to be the interpersonal relationships and technical facility of the research organizations. A further research shall be focused on the institutional framework for the cooperation between the private and public sector in the Czech Republic and its comparison with frameworks used in other EU member countries.

### **Abstract**

*The aim of this paper is to provide the evidence about the difference between structural gravity equation estimated as a fixed effect model compared to the newest methodology by Piermartini and Yotov (2016) on case of bilateral trade flows between the EU and BRICS countries. Using the fixed effect model, we found that using country-time specific factors can significantly increase the effect of some country-pair characteristics. Using the PPML estimator, we found a significant positive effect of the common border for the EU exports and colonial relationship for BRICS exports. we proved that the only estimation technique which offers the correct and unbiased gravity estimates is using the exporter-time, importer-time, and country-pair fixed effects.*

**Keywords:** BRICS, European Union, international trade, panel data, structural gravity model

### **1. Introduction**

Trade relations among the developed and developing countries were significantly affected by globalization process during last decades. Many developing countries went through the economic transformation that enabled to create new trade relations with the EU members and other developed countries. Brazil, Russia, India, China and South Africa (BRICS) belong to those countries as well. During last two decades, these countries have become the regional giants with a great economic and political power. Russia and China have even considerably influenced the global relations that were dominated by the United States of America and European Union until that time.

Since the new millennium, the above-mentioned five emerging countries have developed closer economic and trade relations with each other in order to increase their economic power in the global economic system. Although the BRICS group was officially established only in 2010, the story of BRIC (without South Africa membership) began already in 2001 when Jim O'Neill, chief economist at Goldman Sachs, published an article called *Building Better Global Economic BRIC*. He expressed the opinion, as it turned out correctly, that BRIC political, economic and military power will increase in the following ten years and that especially China will have a significant impact on global economic changes.

Political and structural changes in BRICS during late 1980's and 1990's and their following tremendous economic growth had a significant effect on size and structure of the global world. For this reason, the European Union, advocating the progressive abolition of trade restrictions and lowering customs and other trade barriers in the long term, revised its position towards BRICS members to support the development of new trade relations. For those reasons, we will

estimate the structural gravity equation on the sample of bilateral trade flows between the EU and BRICS countries.

The paper is organized as follows: in the sub-chapter 1.1, we elaborate the newest findings and best estimation techniques of the structural gravity equation.

### ***1.1 Improvements of the Gravity Model Estimation***

The research provided in this paper is based on current knowledge of the theory of international trade, trade policy and econometric modelling of international trade flows using structural gravity model, a work-horse of international trade analysis. On the case of bilateral trade flows between the European Union and BRICS countries, we will show the difference between the structural gravity equation estimated as a fixed effect model compared to the newest methodology presented by Piermartiny and Yotov (2016). After the decades of solving the theoretical impediments of the gravity model, the issues of correct estimation of the gravity equation came to the forefront. In this paper, we will present the newest approach of Piermartini and Yotov (2016) and apply their method to bilateral trade flows between the EU and BRICS countries. These authors dealt not only with the correct specification of the gravity equation but also with the econometric issues that were overlooked for a long time but have a significant effect on the efficiency of the gravity estimates.

The gravity model has been used for decades in international trade and it has become one of the most popular tools for economic analysis. Its main purpose is to explain the extent of bilateral trade flows among countries. The theory behind the gravity model stands on Newton's general theory of gravitation (Fojtíková, 2013), which was transformed and applied to the economic science based on the assumption that the volume of trade between two countries depends on their size and distance. It was assumed that economic size has a positive effect on their mutual trade, while the distance representing a certain barrier to trade affects trade negatively. As Ševela (2002) claims, larger objects that are closer to each other should show stronger trade relationships.

Since papers of Anderson and van Wincoop (2003, 2004), it was considered that the problem of multilateral trade resistance was solve once for all. The correct gravity estimation should always include multilateral resistance terms (MRT). Baldwin and Taglioni (2007) call the omission of the MRT as a gold medal mistake of the gravity model estimation. Therefore, several methods how to estimate their effect were established. In the following research, we will use an approach based on Feenstra (2004) consisting of country fixed effects, which was improved by Olivero and Yotov (2012) by accounting for time effect. Their combination resulted in the newest approach to the gravity model estimation that is based on the exporter-time and importer-time fixed effect. We will show how using this approach will accommodate all other country-specific time-variant characteristics such as unilateral (e.g. export subsidies) or non-discriminatory trade policies (e.g. most favored nation tariffs). Moreover, as using fixed effect is important to address multilateral resistance issue, it is not possible to observe country-specific trade policies.

Estimating the zero trade flows between the country pairs used to be also a big challenge. Despite the fact that this issue usually appears when estimating disaggregated trade data, this effect may appear even on the aggregated level when estimating trade flows among developing countries in the long time horizon. Using the OLS estimator in logarithmic form, the zero trade flows will be simply dropped from the estimation sample. However, they can keep important information. To address this issue, we use the multiplicative form of the gravity equation by non-linear Poisson Pseudo-Maximum Likelihood estimator, which is advocated as the best

solution in a paper of Santos Silva and Tenreyro (2006). Piermartini and Yotov (2016) emphasized additional benefits of PPML estimator. As the trade data are full of heteroscedasticity, using the log-linear OLS estimator offers not only biased results but also inconsistent estimates, while PPML estimator accounts for heteroscedasticity.

The issue of endogeneity rises up when using several variables representing trade policy. To explain the problem of endogeneity in the gravity model estimation, one can imagine the example of reverse causality that two countries, which trade high values of goods between each other, are more likely to liberalize their mutual trade relations, *ceteris paribus*. Baier and Bergstrand (2007) advocate the use of country-pair fixed effects to account for the unobservable relations between the endogenous trade policy covariates with the error term in the gravity equations. Moreover, country-pair fixed effects will also account for any other unobservable time-invariant trade cost components. The last issue connected to trade policy effect estimation is the trade policy time inconsistency as trade policy decisions are not reflected in international trade immediately. Therefore, some papers use different types of time intervals. According to Olivero and Yotov (2012), the most promising are estimates gained from 3-year and 5-year interval trade data.

## 2. Problem Formulation and Methodology

The origin of the gravity model was empirically defined based on international trade flows analysis and therefore it missed any theoretical foundations during the first year of its existence. James E. Anderson was one of the first economist dealing with the theoretical foundation of the gravity equation applied to commodities. Anderson himself admits that „*its use (gravity equation) in economic policy is greatly disturbed by his undefined properties*“ (Anderson, 1979).

We follow derivation of the structural gravity equation by Anderson based on assumptions of Armington's product differentiation and constant elasticity of substitution. Theoretical structural gravity equation:

$$M_{ij} = \frac{Y_j Y_i}{Y^w} \left( \frac{t_{ij}}{P_j \Pi_i} \right)^{1-\sigma} \quad (1)$$

where imports of good  $M_{ij}$  purchased by country  $j$  from country  $i$  are given by income of importing country  $Y_j$ , production possibilities of the country of export  $Y_i$ ,  $Y^w$  defines world nominal income,  $t_{ij}$  represents transportation costs as a representative to barriers to trade and  $\Pi_i$  and  $P_j$  represents multilateral resistance terms. Considering only the trade between two countries, the income of country  $i$  gained from tradable goods sold to country  $j$  equals expenditure on imports of country  $j$  originating in country  $i$ , where:

$$(\Pi_i)^{1-\sigma} = \sum_{j=1}^N \left( \frac{t_{ij}}{P_j} \right)^{1-\sigma} \frac{Y_j}{Y^w}, \quad (2)$$

$$(P_j)^{1-\sigma} = \sum_{i=1}^N \left( \frac{t_{ij}}{\Pi_i} \right)^{1-\sigma} \frac{Y_i}{Y^w}, \quad (3)$$

are multilateral trade resistance terms showing the exporter's and importer's joint average trade barriers which both of them face with all of their possible trading partners.

## 2.1 Model and Data

In this section, we provide a detailed description of variables and explain all gravity equations that will be used in the following part reflecting the newest findings of the gravity methodology. Gravity models are usually very demanding on data inputs that provide an advantage of precise and stable estimations, however, it is cumbersome for data collection and correct data treatment. It is necessary to control for many effects that may not be significant per se but may influence final estimates of other variables.

In 2016, Piermartini and Yotov published a paper containing new approaches and best practices of the panel data gravity estimations. They formulated several recommendations to obtain reliable estimates of partial equilibrium model on aggregated data, which are theoretically consistent with the econometric specification. Their work is based on the foundations of structural gravity model derived by Anderson and van Wincoop (2003) who used a non-linear least squares estimation method, that recently appeared to be the most correct one, although it was hardly followed.

There are many other methods of gravity model estimation that are commonly used. The fixed and random effect models are based on the OLS methodology which has, however, several drawbacks that are very often the subject of criticism from an econometric point of view. Therefore, we chose the Poisson Pseudo-Maximum Likelihood (PPML) method as the main estimation method because it offers certain properties that help to overcome issues that usually accompany gravity estimations, hence this method should be never omitted when running the model. The PPML estimator is based on the maximum likelihood estimate of a Poisson distribution. In other words, it generates the parameter that maximizes the likelihood of the sample accounting for the exponential distribution. And this is the PPML biggest power because the gravity model data usually suffer from heteroscedasticity issues. Let us assume that we derive the gravity equation in the logarithmic form from the structural gravity equation of Anderson and van Wincoop (see equation 1). Adding a multiplicative error term  $e_{ij}$ , we get:

$$\ln M_{ij} = \ln Y_j + \ln Y_i - \ln Y^W + (1 - \sigma)[\ln t_{ij} - \ln P_j - \ln \Pi_i] + \ln e_{ij}, \quad (4)$$

where the mean of  $\log e_{ij}$  depends on higher-order moments of its distribution (Santos Silva and Tenreyro, 2006). If the error term is heteroskedastic, which is highly probable in the gravity models, the expected value of the error term depends on one or more regressors as it includes the variance term, hence our estimates would be biased and inefficient. Shepherd (2013) emphasizes that this kind of heteroscedasticity can be dealt with neither by applying a robust covariance matrix estimator since it affects the parameter estimates in addition to the standard errors. However, Santos Silva and Tenreyro (2006) suggest using the PPML method as an alternative to the log-linear OLS methods.

We will apply the methodology of Piermartini and Yotov (2016) which will be used to estimate the untapped trade potential between the EU and BRICS countries. We will use (i) panel data, (ii) time intervals that were set to three years, (iii) country-specific time-varying fixed effects, (iv) country-pair fixed effects, and (v) PPML estimator. To gain comparable results and analyse the effect of the most modern gravity estimation approaches, we will begin with the traditional OLS estimation of gravity equation:

$$\begin{aligned} \ln M_{ijt} = & \beta_0 + \beta_1 \ln Y_{it} + \beta_2 \ln Y_{jt} + \beta_3 \ln dist_{ijt} + \beta_4 \ln contig_{ijt} + \\ & \beta_5 \ln landlocked_{ijt} + \beta_6 \ln comlag_{ijt} + \beta_7 \ln colony_{ijt} + \beta_8 \ln cmea_{ijt} + \beta_9 \ln wto_{jt} + \\ & \beta_{10} \ln fta_{ijt} + \beta_{11} \ln eu_{memb}_t + \beta_{12} \ln eur_{usd}_t + \beta_{13} \ln lncy_{eur}_t + \beta_{14} \ln near\_wa_{ijt} + \varepsilon_{ijt}. \end{aligned} \quad (5)$$

The variable  $Y_{it}$  and  $Y_{jt}$  represent the size of trading countries and  $dist_{ijt}$  their bilateral distance. The variable  $contig_{ijt}$  means common border,  $landlocked_{ijt}$  represents landlocked country,  $comlag_{ijt}$  a common language, variable  $colony_{ijt}$  their colonial relationship, and  $cmea_{ijt}$  the membership in the Council of Mutual Economic Assistance in the past. In the case of trade policy variables, we use  $wto_{ijt}$  for the WTO membership,  $fta_{ijt}$  for a preferential trade agreement,  $eu\_memb_t$  for the EU membership,  $eur\_usd_t$  as Euro per USD exchange rate,  $lcy\_eur_t$  as local currency per Euro exchange rate and  $ear\_wa_{ijt}$  is effective applied tariff rate. Finally, the variable  $\varepsilon_{ijt}$  represents the error term, which captures all unobserved factors influencing their bilateral imports.

According to Piermartini and Yotov (2016), including the time dimension in gravity equation, one has to estimate multilateral resistance terms as exporter-time  $\pi_{it}$  and importer-time  $\chi_{jt}$  fixed effects to capture the dynamic of the gravity model. It is important to note that using exporter-time and importer-time fixed effects will absorb the size variables ( $Y_i$  and  $Y_j$ ) as well as all other observable and unobservable country-specific characteristics which vary over time:

$$\ln M_{ijt} = \pi_{it} + \chi_{jt} + \beta_1 \ln dist_{ijt} + \beta_2 contig_{ijt} + \beta_3 landlocked_{ijt} + \beta_4 comlag_{ijt} + \beta_5 colony_{ijt} + \beta_6 cmea_{ijt} + \varepsilon_{ijt} \quad (6)$$

Because of its favourable properties, we will reformulate the equation 6 in the multiplicative form and re-estimate it by applying the PPML estimator:

$$M_{ijt} = \exp([\pi_{it} + \chi_{jt} + \beta_1 \ln dist_{ijt} + \beta_2 contig_{ijt} + \beta_3 landlocked_{ijt} + \beta_4 comlag_{ijt} + \beta_5 colony_{ijt} + \beta_6 cmea_{ijt}]) * \ln \varepsilon_{ij} \quad (7)$$

The final stage of the gravity equation also includes the country-pair fixed effects  $\mu_{ij}$  that are able to control for endogeneity of covariates. However, their drawback is that they will absorb all bilateral time-invariant variables, that are used in the structural gravity equations:

$$M_{ijt} = \exp(\pi_{it} + \chi_{jt} + \mu_{ij}) * \ln \varepsilon_{ij} \quad (8)$$

Final estimates of the gravity equations are thus the country-time and country-pair specific, absorbing all time-variant and country-pair fixed observable and unobservable effects on bilateral trade flows. It means that all attributes, effects, and characteristics of countries and their mutual relations are absorbed in the coefficients that are specific for each country pair. All equations were tested to model misspecification. For this purpose, we used the Ramsey RESET test that detects whether any potential variables are omitted in the model specification. In the results, we will find that the only PPML estimator can pass this test while control for multilateral resistance terms.

### 3. Problem Solution

In this part, we will present the panel gravity estimates according to the methodology of Piermartini and Yotov (2016). Tab. 1 presents panel gravity estimates for both directions of trade flows between the EU and BRICS countries. As presented in sub-chapter 2.1, we estimate gravity equation using traditional OLS method without any panel effects which will serve only as a default model for results comparison. It is important to remind that estimates in the column (1) follow standard results of the gravity literature with a high coefficient of determination of 0.84 and 0.81. Most of the estimates are statistically significant and have the expected sign.

Results provided in the column (2) are estimated by the OLS method using specific country-time fixed effects according to the equation 6, which is consistent with the structural gravity model as it includes the multilateral resistance terms. By definition of the equation, both

exporter-time and importer-time fixed effects absorb all observable and unobservable country-specific characteristics varying over time that may have an effect on bilateral trade. Therefore, the coefficient of determination is higher than in the case of traditional OLS estimation. Using this method, we gain a much higher number of estimated parameters and observations. The estimates reported in column (2) follow the message from the results in column (1) in the sign and significance of variables. However, using country-time specific factors, we can observe that *landlocked<sub>ijt</sub>* and *cmea<sub>ijt</sub>* variables contain the correct sign and have a stronger effect on bilateral imports than traditional estimates of the OLS method. The effect of the common border, language, and former colonial relationships remain insignificant as in the previous results.

Following recommendations of Piermartini and Yotov (2016), the gravity equation 7 includes the full set of exporter-time and importer-time fixed effects re-estimated using the PPML estimator. The PPML estimates of this equation are presented in the columns (3). Using the PPML estimation method, we can make several conclusions that are different from the OLS. First, there is a significant difference in terms of magnitudes, significance and even signs of the estimates which are in line with findings of Piermartini and Yotov (2016) and Santos Silva and Tenreyro (2006). For example, the negative effect of distance is lower in the case of BRICS imports and even insignificant while the effect of the common border had become highly significant. In the case of the EU imports, the effect of distance is similar with the OLS and fixed effects estimates, however, the effect of colonial relationship increased and gained a high level of significance. The magnitude of the CMEA membership remained the same for BRICS imports but significantly decreased in the opposite direction. The p-value of the Ramsey RESET test reported at the bottom of the Tab. 1, reveal that the PPML estimator is the only one able to pass the misspecification test while using multilateral trade resistance terms.

Source: author's calculations (2018).

Finally, the columns (4) include results of the equation 8 that is modified by country-pair fixed effects to address potential endogeneity issues. Due to the perfect collinearity, using the country-pair fixed effects do not allow to include any gravity variables that do not vary over time. Therefore, we obtain more than 360 parameters that represent all specific properties of bilateral trade flows of each country pair. Using this kind of estimation technique, we cannot observe the determinants of bilateral trade flows *per se*, as they are included in the exporter-time, importer-time, and country-pair fixed effects, but we will obtain the best estimation solution of the gravity equation. The results of Ramsey RESET test confirmed the validity of the panel gravity model with a very high coefficient of determination.

#### 4. Conclusion

In this paper, we applied the newest methodology of the gravity model estimation on the sample of bilateral trade flows between the EU and BRICS countries. We found significant determinants of their mutual exchange of goods using the simple OLS and fixed effect estimation, and compared these methods with the most advanced estimation technique using Poisson Pseudo-Maximum Likelihood estimator and methodology of Piermartiny and Yotov (2016). Using a simple OLS estimation helps us to confirm the right way of gravity model estimation as the results have expected size and sign.

We found that using country-time specific factors can increase the effect of some country-pair characteristics, such as landlocked position of the country or former membership in the free trade area, then in case of the default OLS method. The effect of the common border, language, and former colonial relationships remained insignificant in most cases of the OLS estimation. It means that these attributes do not have any meaningful effect on bilateral trade flows between the EU and BRICS countries. Similar results were obtained using the PPML estimator. The only difference is a significant border effect for the EU exports and colonial relationship for BRICS exports. Finally, we proved that the only estimation technique which offers the correct and unbiased gravity estimates is using the exporter-time, importer-time, and country-pair fixed effects.

### Abstract

*The aim of this paper is created the typology of international college students (Generation Y) from the selected countries of European Union (Czech Republic, Slovakia, Bulgaria and Romania), who participated in International Practical Placements, specifically Summer Work and Travel Program in United States of America. Data were obtained by electronic questioning. Typology is based on attitudes and perceptions. This paper discusses the differences in the attitudes and perceptions of the college students to the international practical placements market. Attitudes and perceptions are concentrated into the ten factors, for example the experience with Work and Travel Program, perception of experience, benefits of the program, attitudes to travel. As the research methods the factor analysis and cluster analysis are used.*

**Keywords:** *attitudes, cluster analysis, factor analysis, generation Y, practical placements market*

**JEL Classification:** *A14, C38, M31, Z39*

### 1. Introduction

European higher education institutions have always engaged in a wide range of international activities with partner institutions from around the world, for example program Erasmus+, lectures by international lecturers, organization of international week at the university, internships abroad, excursions abroad (Hvalič-Touzery et al, 2017). These efforts are also being developed by students. Examples of these activities may be international practical placement. One of them is program called as Work and Travel program. This program offers many Czech and foreign agencies. Students can work abroad for up to 4 months and then for up to 30 days to traveling in the country (Czech Us [online], 2018). 332,534 students travelled to the USA in 2015. The largest share of these student is from Europe, second is Asia (Department of State [online], 2016). The aim of the paper is created the typology of international college students (Generation Y) from the selected countries of European Union, namely from Czech Republic, Slovakia, Bulgaria and Romania, who participated in International Practical Placements (Work and Travel Program in United States of America).

Internet connectivity and usage have risen dramatically in the past decade, providing people with easier means for obtaining information, and engaging in economic and social exchanges, (Lissitsa and Kol, 2016, p. 203). Increasing demand for the program is affected by the internet connectivity. Mobile phone development ant the Internet are the factors influencing this market. Mobile phones market is probably the most dynamic of any in the world. Degree and rate of change in technology and product innovation is staggering (Spáčil, 2016). Members of

Generation Y are typically people who were influenced by modern information technologies such as mobile phones (Pawlasová and Klézl, 2017).

The increasing demand for this program may also be based on generational differences. Paper is concentrated into the Generation Y. Generation Y is a collective term used to refer to those born between 1980 and 2000 (Eisner, 2005), also as the Internet or dot.com generation (Wong, Wan and Gao, 2017). Berg and Behrer (2011) describe members of Generation Y as people who were born between years 1980 and 1996. Members of Generation X are highly brand loyal and convinced, members of Generation Y (Millennials) appear to be the very opposite in favour of experimenting and instability (Spáčil and Teichmannová, 2016). Desire to experiment can be transferred to travel. Generation Y possess an extensive and significant purchasing power (Klapilová Krbová and Velčovská, 2016).

Many Generation Y have work experience while being a student before they graduate from school and enter the full-time workforce. It is assumed, therefore, that they have clear expectations about what they want to do, for whom they work, and who they want to be in the future (Wong, Wan and Gao, 2017, p. 142). Economic situation and expectations about personal job situation are dependent on generation, Generation Y is more positive than Generation X except for current situation of their personal job situation (Pawlasová, Spáčil and Valečková, 2014).

## 2. Methodology of the Research

Second chapter contains information about data collection methodology (primary quantitative research), methods of data analysis and theoretical background of factor analysis and cluster analysis.

### 2.1 Data Collection

Analysis is based on primary and quantitative data because it is descriptive research (Malhotra, Birks and Wills, 2012). Population is defined as European students and university graduates from Generation Y from Czech Republic, Slovakia, Romania and Bulgaria who participated in the Work and Travel program. Members of Generation Y are people who were born between years 1980 and 1996 (Berg and Behrer, 2011). Data was collected in spring 2016. Sample contained 288 respondents (quota sampling by country and gender). Quota sampling is suitable for descriptive research. Quota setting was based on J-1 visas issued in 2014. Bulgaria received 6,336 visas, Romania received 5,275 visas, Slovakia received 3,162 visas and Czech Republic received 3,41 visas (see Figure 1). Second applied quota is 50 % for each gender. Obtained data did not meet the quota. It did not balanced sample. Balance was conducted in the SPSS programme.

**Figure 1: Structure of Sample**

Source: Department of State [online], 2016; author's calculations

Primary research contain question on the attitude, country, gender, age and field of study. It was primarily focused on the 10 attitudes questions. Attitudes were measured on seven-point scale. Value 1 expressed agree and value 7 expressed disagree. This interval was chosen regarding the methods of analysis (factor analysis and cluster analysis). It is recommended to use the seven-point scale (Malhotra, Birks and Wills, 2012). Attitude is defined as a psychological and overall tendency to agree or disagree with a situation, after an evaluation process (Dumitrescu, Tichindelean, Vinerean, 2013, p. 468). There are ten statements for factor and cluster analysis, namely they are:

- Statement 1 – I like traveling and I like to meet foreign cultures.
- Statement 2 – I think that Work and Travel program is my best life experience.
- Statement 3 - I think that Work and Travel program improves my CV.
- Statement 4 - I had a lot of work experience abroad before I went to Work and Travel program.
- Statement 5 – Thanks to Work and Travel program I have learned to take care of myself.
- Statement 6 – Work and Travel program brought me some new friendships.
- Statement 7 – Work and Travel program involves many administrative matters.
- Statement 8 – Work and Travel program improved my English language.
- Statement 9 - I think that anyone who did not go abroad has lost a wonderful experience.
- Statement 10 – I have only positive feeling from Work and Travel program.

## 2.2 Data Analysis Method

Data was obtained by interrogation. Data has a quantitative character. Factor analysis and cluster analysis are used to fulfil the aim of the paper. Factor analysis will be used for the reduction of these (ten) statements. Factor analysis was also used to compare outcomes in different countries (Czech Republic, Slovakia, Bulgaria, Romania), results of new factors and comparison of incorporating the variable into new factors (identity and diversity in the country). Cluster analysis will be used for the design typology of international practical placements market.

Factor analysis is used for the reduction the statements. The results of the factor analysis (factor scores) are further used for cluster analysis. Varimax method was used to the factor rotation. New factors were created using Eigenvalue rules (Kaiser's rule). This rule ensures that the number of new factors explain a sufficient amount of file variability. Factor scores (necessary for cluster analysis) were created by regression.

Factor analysis is used in general (i) to identify underlying dimensions or factors, (ii) to identify a new, smaller, set of uncorrelated variables (iii) to identify a smaller set of salient variables from a larger set. Factor analysis has numerous marketing applications; in segmentation, in product research, in advertising studies and in pricings studies etc. (Malhotra, Birks and Wills, 2012)

Factor analysis is like multiple regression analysis. Factor analysis model may be represented as (Malhotra, Birks and Wills, 2012)

$$X_i = A_{i1}F_1 + A_{i2}F_2 + A_{ia}F_a + \dots + A_{im}F_m + V_iU_i \quad (1)$$

where,  $X_i$  =  $i$ th standardised variable,

$A_{ij}$  = standardised multiple regression coefficient of variable  $i$  on common factor  $j$ ,

$F$  = common factor,  
 $V_i$  = standardized regression coefficient of variable  $i$  on unique factor  $i$ ,  
 $U_i$  = the unique factor for variable  $i$ ,  
 $m$  = number of common factors.

Cluster analysis is used to classifying objects or cases into relatively homogeneous groups (segments). Clustering procedures are hierarchical or non-hierarchical. Hierarchical clustering is characterised by the development of hierarchy or treelike structure. Non-hierarchical methods are frequently referred to as k-means (classified as sequential threshold, parallel threshold and optimising partitioning). (Malhotra, Birks and Wills, 2012)

The second step of analysis contains the creation of a typology of the European students from Czech Republic, Slovakia, Bulgaria and Romania with using cluster analysis. Typologies are based on factor scores from factor analysis. Typologies were created based on hierarchical clustering methods (Ward's method and Squared Euclidean distance). Types of customer are further characterized by country, gender, age and field of study.

There are used the Pearson's chi-square test to find out dependency between typologies and country, gender, age and field of study. Chi-square test serves both as a goodness-of-fit test and as a test for the more common contingency table (Hendl, 2006).

Data were first inserted and adjusted in Microsoft Office Excel. Data matrix was further inserted into the IBM SPSS Statistics 25 program. All testing and results are performed at the 5% significance level.

### **3. Problem Solution**

The analysis is divided into three main parts as started in the methodology. The first part is variables reduction using the factor analysis (Chapter 3.1). The original ten variables are reduced to new three factors. After that European students are divided according to attitudes into two types with using the cluster analysis (Chapter 3.2). The third (last part) of the analysis is the characteristic of each types with the using descriptive statistics and Pearson's chi-square test (Chapter 3.2).

#### **3.1 Variables Reduction**

Research included ten variables (statements) namely (1) I like traveling and I like to meet foreign cultures, (2) I think that Work and Travel program is my best life experience, (3) I think that Work and Travel program improves my CV, (4) I had a lot of work experience abroad before I went to Work and Travel program, (5) Thanks to Work and Travel program I have learned to take care of myself, (6) Work and Travel program brought me some new friendships, (7) Work and Travel program involves many administrative matters, (8) Work and Travel program improved my English language, (9) I think that anyone who did not go abroad has lost a wonderful experience and (10) have only positive feeling from Work and Travel program.

Dimensional reduction was conducted to reduce the factors. It was used a factor analysis with extraction by principal components method and rotation Varimax. New factors were created using Eigenvalue rules (named as Kaiser's rule), if Eigenvalues is greater than one. Factor scores were created using regression. Factor scores is the variables using in the second step in cluster analysis.

Kaiser-Meyer-Olkin measure of sampling adequacy is an index to examine the appropriateness of factor analysis. High values (from 0.5 to 1) indicate that factor analysis is appropriate. Values below 0.5 imply that factor analysis may not be appropriate (Malhotra, Birks and Wills, 2012). Table 1 shows results of Kaiser-Meyer-Olkin measure of sampling adequacy for this data. Value is equal 0.829, factor analysis is appropriate.

Bartlett's test of sphericity is test statistic used to examine the hypothesis that the variables are uncorrelated in the population. The population correlation matrix is an identity matrix; each variable correlate perfectly with itself ( $r = 1$ ) but has no correlation with the other variables ( $r = 0$ ), (Malhotra, Birks and Wills, 2012). Results in Table 1 show signification (0.000). Signification is less than 0.05. Zero hypothesis is rejected. The correlation coefficients between the variables are not zero. Factor analysis is suitable for use.

**Table 1: Kaiser-Meyer-Olkin Measure of Sampling Adequacy and Bartlett's Test**

KMO and Bartlett's Test		
Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		,829
Bartlett's Test of Sphericity	Approx. Chi-Square	1126,266
	df	45
	Sig.	,000

Source: own elaboration (2018)

Eigenvalue represents the total variance explained by each factor (Table 2). Based on the eigenvalue criterion (Eigenvalue rule, Kaiser's rule), again three factors are extracted (based on ten variables or statements).

Percentage of variance is the percentage of the total variance attributed to each factor. The first factor accounts for 44.76 % of the variance, the second accounts for the 13.52 %, the third factor account for 10.24 % of the variance. Three factors explain a total 68.53 % of the variance. Malhotra, Birks and Wills (2012) say that it is recommended that the factors extracted should account for at least 60 % of the variance. This requirement is met.

**Table 2: Variance Explained**

Component	Total	Initial Eigenvalues		Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings		
		% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	4,476	44,761	44,761	4,476	44,761	44,761	2,925	29,246	29,246
2	1,352	13,525	58,286	1,352	13,525	58,286	2,795	27,953	57,200
3	1,024	10,245	68,530	1,024	10,245	68,530	1,133	11,331	68,530
4	,795	7,954	76,484						
5	,675	6,752	83,237						
6	,480	4,799	88,036						
7	,425	4,254	92,290						
8	,349	3,485	95,775						
9	,277	2,775	98,550						
10	,145	1,450	100,000						

Extraction Method: Principal Component Analysis.

Source: own elaboration (2018)

Table 3 shows the factor matrix after rotation (orthogonal rotation, varimax procedure). Orthogonal method of rotation minimises the number of variables with high loadings on a factor thereby enhancing the interpretability of the factors (Malhotra, Birks and Wills, 2012).

Factor loadings in the matrix represent the correlations between the factors and the variables. The first factor includes these original factors (new factor name: **improved skills through Work and Travel program**):

- Statement 2 – I think that Work and Travel program is my best life experience.
- Statement 3 - I think that Work and Travel program improves my CV.
- Statement 5 – Thanks to Work and Travel program I have learned to take care of myself.
- Statement 8 – Work and Travel program improved my English language.
- Statement 10 – I have only positive feeling from Work and Travel program.

The second factor includes three these original factors (new factor name: **passion for traveling**):

- Statement 1 – I like traveling and I like to meet foreign cultures.
- Statement 6 – Work and Travel program brought me some new friendships.
- Statement 9 – I think that anyone who did not go abroad has lost a wonderful experience.

The third factor includes these original factors (new factor name: **experience gained before Work and Travel program**):

- Statement 4 - I had a lot of work experience abroad before I went to Work and Travel program.
- Statement 7 – Work and Travel program involves many administrative matters.

**Table 3: Rotated Component Matrix**

**Rotated Component Matrix<sup>a</sup>**

	Component

### 3.2 Typology of the European Students in Work and Travel Program

This Chapter contain analysis of attitude to Work and Travel program of European students. Students are divided according to attitudes into 2 types with using the cluster analysis. The types are then characterized by country, gender, age and field of study. The differences are analysed with using the descriptive statistics and Pearson’s chi-square test.

Hierarchical cluster analysis was used to determine an appropriated number some clusters. It was used a Ward’s method and interval measure, concretely Squared Euclidean distance. Using these methods, it was decided to create the two clusters of European students on international practical placement market.

The first cluster is named as **Adventurers**. Attitudes of these students are that they like meet foreign cultures and traveling, Work and Travel program brought some new international friendships.

The second cluster is named as **Pragmatic**. Main differences from the first segment is that pragmatic see Work and Travel program as the best life experience because it improves the CV and English language. They state that the program includes many administrative matters. Pragmatists consider the benefits and demands too. Pragmatists are more rational. Adventurers are more emotional. Mean values of factor score by cluster are in the Table 4.

**Table 4: Mean Values of Factor Score by Clusters**

Cluster Number of Case	Mean		
	REGR factor score 1 for analysis 1	REGR factor score 2 for analysis 1	REGR factor score 3 for analysis 1
Adventurers	,3380384	-,5238486	,4932585
Pragmatic	-,4011197	,6216041	-,5853055
Total	,0000000	,0000000	,0000000

Source: own elaboration (2018)

Dependences between typology and gender, age, country and field of study are tested using Pearson’s chi-Square test. Statistical testing is carried out at the 5% significance level. Significance for gender is equal 0.1, significance for age is equal 0.035, significance for country is equal 0.821 and significance for field of study is equal 0.322. There is statistical significance between typology and age. There is not statistical significance between typology and gender, country and field of study. Frequencies by the age are listed in the Table 5. There is the trend that adventurers are younger, and segment of pragmatics includes older respondents (see Table 5).

**Table 5: Crosstabs of Segments by the Age**

	Age			Total
	20 - 23	24 - 26	27 and more	
Adventurers	55,2%	58,8%	21,4%	54,3%
Pragmatic	44,8%	41,2%	78,6%	45,7%

Source: own elaboration (2018)

## 4. Conclusion

The aim of this paper is created the typology of international college students (Generation Y) from the selected countries of European Union (Czech Republic, Slovakia, Bulgaria and Romania), who participated in international practical placements, specifically Summer Work and Travel program in United States of America.

Research was based on primary and quantitative data. Data was obtained by questioning (electronic) in 2016. Population was defining as European students and university graduates from Generation Y from Czech Republic, Slovakia, Romania and Bulgaria who participated in the Work and Travel program.

Factor analysis was used for the reduction the original statements. There are three new factors, namely (i) improved skills through Work and Travel program, (ii) passion for traveling and (iii) experience gained before Work and Travel program. The results of the factor analysis (factor scores) were further used for cluster analysis.

Hierarchical cluster analysis was used to determine an appropriated number some clusters. Using these methods, it was decided to create the two clusters of European students on international practical placement market. The first cluster was named as Adventurers and the second cluster was named as Pragmatic. Adventurers are younger, and segment of pragmatics includes older respondents.

Two types of participants were identified. These types may have different behaviours. These differences will be part of the further research. It will focus on the purchasing decision making process, namely differences in problem recognition, information search, decision making, purchase and post-purchase behaviour.

### **Abstract**

*The European Union's main objective is to promote peace, follow the EU's values and construct Europe as a single economic space. There are many indicators to compare countries or regions including gross domestic product (GDP), gross national income (GNI), and others. The aim of this paper is to identify the homogeneity of these indicators in the European Union (across all member states) in three years – 1995, 2005 and 2015. The results identify the difference in a country's position over time and whether nation's resources are put to capital creation or declining towards abroad, too. To identify the presence of spatial structure, Moran's I and LISA are used. The other classical statistical methods we have used are K-W test or correlation coefficients.*

**Keywords:** comparison, GDP, GNI, spatial autocorrelation, the European Union

**JEL Classification:** F41, F43, F62, C21

### **1. Introduction**

The European Union (EU) is the outcome of a process of integration that started in 1950 with six original states (France, West Germany, Italy, The Netherlands, Belgium, and Luxembourg). It is a unique model of integration based on treaties among member states which created an institutional framework (Lyberopoulos, 2000). The establishment of the European Union is a combination of economic, monetary, social, cultural, and political relations bringing the member states closer together and leading to the implementation of common goals and values.

The EU countries are considered to be one of the world's most prosperous economic areas, however there are large economic disparities between its individual member states. The income disparities in the EU countries are important fields of the research of many authors, e.g. Grossman (2004), Peterson (2004) or Badircea et. al. (2016).

The paper focuses on measuring the income disparities using 2 basic macroeconomic indicators - gross domestic product (GDP) per capita and gross national product (GNI) per capita in the EU countries and on assessing their development during the existence of the European Union. The results of three years 1995, 2005, 2015 are evaluated using Moran index which is complemented by classical statistical methods, see Kotulic et. al. (2016), Sira, Vavrek, Pukala (2017), Stefko et. al., Vavrek (2017) or Vavrek, Kotulic, Adamisin (2015).

### ***1.1 Economic Integration as an Accompanying Phenomenon of the European Union***

Economic integration means that the economies of different countries are linked, and the trade barriers are eliminated within an area (Balassa, 1962). According to a business dictionary, economic integration means the elimination of tariff and non-tariff barriers to the flow of goods, services, and factors of production between a group of nations, or different parts of the same nation. Machlup (1977) designated also the first user of the term “economic integration”. Finally, in the contemporary economic theory, the economic integration is defined as the unification of economic policies among different states through the partial or full abolition of tariff and non-tariff restrictions on trade taking place among them prior to their integration (Baldwin, Wyplosz, 2008). Economic integration refers to the various types of agreements coordinating economic policies and regulations among countries. There has been a rapid increase in the number of regional trade agreements (RTAs) since the mid-1990s and the appetite for deep integration was reflected in the growth of European Union (EU) membership (Larue, 2018). Economic integration was a priority for all states without precisely defined competences of the European Communities and the member states. The system of economic integration has begun to change into a system of monetary integration, economic coordination, and a system of common policies (Paskrtova, Stolicna, Novackova, 2016). The goal of economic integration is the promotion of mutual trade and the increase of the level of welfare while leading to the increase of economic productivity of the states (Dalimov, 2009).

At a macro level, it is possible to find several forms of economic integration based on Balass (1961) including the following: Free trade area – tariffs and quantitative restrictions are abolished in the trade with goods and services, individual countries keep their own tariffs towards non-members. Customs union – apart from abolishing tariffs and quantitative restrictions, a common tariff is set for non-members. In a customs union, member states are joined in one commercial-political area in relation to the outside world. Common market – abolishment of trade restrictions but also different restrictions of the freedom of movement of production factors - a free movement of capital and labour. Economic union – provisions as by a common trade and moreover unification or at least a certain level of harmonization of economic policies in order to eliminate discrimination arising from the differences in these policies across individual countries. Monetary union – it assumes common currency which would reflect economic and finally also political union of member states. Complete economic integration – it assumes unification of monetary, fiscal, social and stabilization policies and requires the creation of a transnational governing body, the decisions of which are binding for all member states. Complete economic integration should result in a political union.

According to Allen (1963), economic integration involves at least two countries to abolish customs tariffs on the inner border between the states. Main benefits for the integrating countries include a free access to markets of the other member states and the increase of productivity. The regional integration in Europe not only affects static efficiency but can also have economically and statistically significant growth effects (Henrekson, Torstensson, Torstensson, 1997).

## **2. Problem Formulation and Methodology**

The subject of the analytical part of the given paper is the evaluation of 28 member states in the European Union (to 1.1. 2018) with the emphasis on the identification of the influence of a membership on the performance of its national economies. Selected macroeconomic indicators (GDP per capita, GNI per capita) are evaluated separately in two years, particularly

in the year 1995 and 2005 (the last enlargement of the members was in 2013) and the results obtained in such a way are subsequently compared with the aim to identify the differences in the performance of the countries also as a result of their EU membership. The countries are divided into two groups in particular years depending on whether or not they were members of the EU in the current year.

The differences among the groups of countries in the analysed years are monitored using selected moment characteristics. The differences between the GDI per capita values and GNI per capita values in particular years are monitored using the Mann-Whitney test. The results in the individual years which are modified by the GDP deflator are compared in pairs and also evaluated with the Sign test.

The last part is the monitoring of the differences in space in each of three given years. Since by using the Shapiro-Wilk test, the normality of the monitored parameters was not confirmed, a median was used as a mean value for the purposes of spatial autocorrelation. To monitor the spatial relations among the states regardless of their EU membership, the Moran's index and LISA were used:

The analyses are processed using publicly available data via the World Bank. The analyses are performed in the MS Excel and statistical software Statgraphics and Statistica.

### 3. Problem Solution

The growth of national economies as well as economic unions as a whole (e.g. the EU) is a current trend we can observe across the whole Europe. We assume that country's membership in such a union can have a positive influence on the development of its macroeconomic indicators over time.

**Figure 1: Comparison of Non-EU Member and EU Member Countries in 1995**

Source: author's calculations

In 1995, statistically significant differences among the countries that are, or, are not the EU members, were confirmed using GDP per capita ( $W = 195$ ;  $p \leq 0,01$ ), or GNI per capita ( $W = 180$ ;  $p \leq 0,01$ ). No GDP per capita of any of the countries outside the EU reaches the level of the EU members, with Cyprus being the country with the highest GDP per capita of 11488 EUR in this group. The best rated country in this year is Luxemburg with the GDP per capita almost 5 times higher compared to the values of Cyprus. Similar results can be observed also by the evaluation of the groups using GNI per capita as illustrated in Figure 1.

**Figure 2: Comparison of Non-EU Member and EU Member Countries in 2005**

Source: author's calculations

Again, the differences between the groups of countries ( $W_{GDP} = 72$ ,  $p \leq 0,05$ ;  $W_{GNI} = 71$ ,  $p \leq 0,05$ ) were confirmed. But as illustrated in Figure 2, the differences were not so considerable as in the year 1995. The main cause can be seen in the EU enlargement by 10 countries in 2004, the national economies of which did not have enough time to use the advantages of the membership in EU. The values in the group of the EU member states has improved in average with both indicators by more than 2000 EUR ( $\Delta_{GDP} = 2233$  EUR,  $\Delta_{GNI} = 2067$  EUR), which in combination with a decrease of the mean value of median indicates a positive skewness of the overall results.

### 3.1 Comparing the Indicators at the Level of Individual Countries

In the previous part, the difference between the groups of the EU member states and non-EU member states in a given period was monitored. In this part, the attention is paid to the changes between the years 1995 - 2005 and 2005 - 2015 at the level of individual countries with the focus on the changes caused due to the country's membership in the EU.

**Table 1: The Differences in Paired Comparison of Individual Countries**

	GDP per capita	GNI per capita
<b>1995 vs 2005</b>	5,10**	3,59**
<b>2005 vs 2015</b>	5**	3,59**

\*\*  $p \leq 0,01$

Source: author's calculations

After 10 years, we can observe statistically significant changes (Table 1), by the comparison using GDP per capita as well as GNI per capita. The same conclusions, i.e. the differences in comparing the pairs of years, can be observed also in the groups of countries, the status of which has not been changed in the given period, i.e. they were the EU member states in both monitored years. After the year 2005, only three countries joined the EU (Bulgaria, Romania, and Croatia) and their achieved results are not statistically different.

**Table 2: The Influence of the Country’s Status on the Evaluation of the Countries**

	Original data				GDP deflator used			
	GDP per capita		GNI per capita		GDP per capita		GNI per capita	
Change	Yes	No	Yes	No	Yes	No	Yes	No
1995 vs 2005	2,85**	4**	1,15	4,69**	1,58	3,06**	1,33	3,06**
2005 vs 2015	1,15	3,2**	1,15	2,8**	0	1,2	0	1,2

\*\* p ≤ 0,01

Source: author’s calculations

After using the GDP deflator, we observe the differences in the comparison of the pairs of years in the individual groups of countries. The change of the status of the countries did not cause the changes either in the values of GDP per capita or in the values of GNI per capita (Table 2) except data (respectively the structure of data) illustrated in Figure 3.

**Figure 3: The Differences Identified by Paired Comparison**

1 – country status changed 2 – country status not changed

Source: author’s calculations

### 3.2 Comparing the Indicators in Space

We assume that the EU membership brings also positive influence, the externalities that are subsequently reflected in the performance of the economies. When comparing the achieved results from the previous analyses, we can state that these results are considerably similar by using GDP per capita or GNI per capita. By the evaluation of these indicators in space, the EU countries are considered as a united area based on which a spatial matrix is created for the needs of Moran’s index.

From the point of view of a geographical distribution of these regions and despite the above identified differences, it is not possible to statistically confirm a significant spatial autocorrelation in all three monitored years by using GDP per capita as well as GNI per capita

**Table 3: Spatial Autocorrelation GDP per Capita, GNI per Capita**

LISA		GDP per capita / GNI per capita
1995	max	Germany
	min	Slovakia
2005	max	Belgium
	min	Slovakia
2005def	max	Belgium
	min	Hungary
2015	max	Belgium
	min	Hungary
2015def	max	Belgium
	min	Hungary

Source: author's calculations

The Moran's index in all three cases has achieved the values limiting to null, based on which we can consider these results as accidental or as spatially uncorrelated. Based on these results, we can still find clusters at a local level using LISA indicator (Table 3).

#### 4. Conclusion

We confirm the results of the previous research (Vavrek, Ardielli, Gonos, 2016), i.e. the evaluation of the countries based on selected macroeconomic indicators is a method often used in practice nowadays, the advantage of which is mainly a simple and basic comparison of national economies. These indicators may also include GDP per capita as well as GNI per capita. In practice, the comparison of countries (not groups of countries) is used since in the structure of the European Union, it is not possible to find a group homogenous from the point of view of several macroeconomic or social characteristics. Despite the intention to create a united European area, it is possible to observe significant differences in the comparison of individual countries which considerably determines the fulfilment of this vision. For more detailed results, we recommend comparing countries using more parameters, MCMD methods, cluster analysis or other methods of higher-order statistics. Based on above given analyses, it is not possible to claim that the country's membership in the EU will automatically positively influence the performance of an economy. In the future, the question of the advantageousness of the entry or exit from the European Union is drawn where a long-term membership in the EU expressed by comparing the years 1995, 2005, and 2015 is not a significant contribution for a country from the point of view of the development of GDP per capita and GNI per capita. Although these two indicators are methodologically different, these differences did not affect the results of the individual analyses.

### **Abstract**

*The paper is focused on food quality perception in the context of product origin in European Union countries from the perspective of Baby Boomers generation. Its aim is to discover whether consumers of this generation consider food product origin as an indicator of product quality, to analyse the role of product origin in their purchase decision, to identify preference for product origin, to compare perceived quality of products originating from the Czech Republic or other European Union countries, and to identify European Union countries associated with high-quality and low-quality food. Theoretical background is related to impact of country of product origin on product quality perception, also generation Baby Boomers is characterized. In empirical part, the results of research study are presented. A total of 206 Baby Boomers respondents in the Czech Republic were interviewed. Chi-square test was undertaken to determine whether the way how consumers perceive the food quality and origin depends on their socio-demographic characteristics.*

**Keywords:** *Baby Boomers, consumers, European Union countries, food products, food quality, product origin*

**JEL Classification:** *M31, L66, Q18*

### **1. Introduction**

Increasing consumer interest in food products origin is observed worldwide as a countertrend against the globalisation or as the result of the food safety scandals across the Europe over the past years. Publicized affairs shook consumer confidence in the quality and safety of food, e.g. biscuits contaminated with poison, food containing industrial salt, Salmonella in minced pork and beef, fruits containing pesticides, or cucumbers and sauerkraut with formic acid can be mentioned as examples on the Czech food products market (Czech Agriculture and Food Inspection Authority [online], 2018). For the last few years, the problem is also dual food quality. Discussion on the topic of different quality of food intended for the old and new member states of the European Union (EU) are officially conducted at least since 2011, when the Association of Slovak Consumers published a comparison of the same foods purchased in eight EU countries. In some cases, it turned out that in the markets of traditional EU countries (Germany and Austria) is offered goods having a better quality than in the new member states of the EU, including also the Czech Republic. According to the conclusion of the European Commission responding to this situation, food producers can change their products in the light of both, the market specifics and consumer preferences of individual EU member states. The only condition is to provide true information on the packaging (dTest [online], 2016). As a result, consumers are more interested in the origin of the food they buy. Also, their preferences of products from the domestic country are increasing (Velčovská, 2018).

The importance of product origin can vary in different age group of consumers, with particular tendency of older consumers to prefer domestic products (Marzilli [online], 2017). To the best of the authors' knowledge, a study analysing the topic from the perspective of Generation Baby Boomers is missing. Therefore, the paper is focused on this age cohort. Its aim to discover how Baby Boomers consumers perceive food quality in the context of product origin and what their preferences for product origin are. After the theoretical background of the topic, the methodology of the research is explained and research findings are discussed.

### ***1.1 Country of Product Origin***

There are many factors with influence on the consumer perception of food quality, e.g. price, packaging, brand, etc. Due to the growing globalization of markets bringing foreign competitors and exposing consumers to a wide range of foreign products, a crucial information cue, used by consumers as a measure of product quality, is country of origin (Velčovská, 2018; Kalicharan, 2014; Jarossová and Pazúriková, 2014).

The impact of country of origin depends on several variables. Important drivers are country image, national stereotypes, consumer ethnocentrism and animosity, brand familiarity and experience, type of product, and product involvement (Yang, Ramsaran and Wibowo; 2016). Some products are associated with a particular country owing to their legacy, culture or lifestyle, which automatically leads to perceive them as premium, e.g. French wine, Czech beer, Netherland cheese or Belgian chocolate. Other studies have shown that consumers tend to have a relative preference for or aversion against products originated from certain countries as they are influenced by the country image (Oberecker, Riefler and Diamantopoulos, 2008). On the other hand, people are often ethnocentric and favourably predisposed to their own country's products. These consumers will probably rate their country's products more favourably than those made in foreign countries (Baker and Ballington, 2002). Impact of country image on consumers' perception of product quality was surveyed e.g. by Kalicharan (2014), Yang, Ramsaran and Wibowo (2016). Image of the EU among Czech consumers was specifically examined in the research of Pawlasová, Spáčil and Valečková ([online], 2014).

Country of origin has a particularly significant impact in situation when the consumer decides between alternatives, compares the characteristics of similar products and finds that one of them comes from a country known for its high-quality products. The probability of purchasing this product made in a positively perceived country is much higher in comparison with competitive products (Kalicharan, 2014). Since the fact that brand strength is gaining the customers, their trust and loyalty (Kozel, Vaněk and Očko, 2016), country of origin effect is stronger in situations where consumers do not know much about the brand, where additional information is unavailable or difficult to get (Cristea, Capatina and Stoenescu, 2015).

Researchers underline the country of origin effect on consumers' purchase intention (e.g. Kalicharan, 2014; Yang, Ramsaran and Wibowo; 2016; Phau, Wang and Yang, 2008). However, Paul and Dasgupta (2010) argue that this effect may be indirect, mediated by four factors: brand awareness, brand associations, brand loyalty and perceived quality.

To obtain more complete information on the topic, it can be useful to look at the findings of the Special Eurobarometer survey from 2012, carried out in the EU member states on a sample of 26 593 respondents aged 15 years and over. The study was not directly focused on Baby Boomers consumers, however the 55+ age group, substantially corresponding with age boundaries of Baby Boomers, was included. Three quarters (76%) of EU citizens in the age 55+ see the product origin as important when buying food, what is noticeably higher value in

comparison with younger consumers aged 15-24 (only 57 % of them consider product origin as important) (European Commission [online], 2012). Also Marzilli ([online], 2017) confirms a higher interest of older consumers in product origin, 80 % of them (and only 68 % of Millennials) want to know where the products were manufactured. To compare the importance of product origin for respondents aged 55+ in individual EU countries, there are missing more detail data in the Eurobarometer study, only results for whole sample of respondents (15+) are available (data for the age category 55+ are traceable only across the EU, not for individual countries). In every EU member state except the Netherlands (47%), more than half of respondents regard the geographical origin of food products as important, but there are significant differences between levels of importance in individual states. The vast majority of respondents in Greece (90%) and Italy (88%) consider product origin as important, while in Belgium (56%) this proportion is substantially lower. In other EU countries, the importance of product origin ranges between 62 – 81 %, in the CR it is 80 % (European Commission [online], 2012).

An importance of factors affecting food choice specifically in the Czech food products market was analysed within the survey „Food and Czech consumer“ conducted in November 2015 on the sample of 1019 respondents 18+. The product origin is important for 39 % respondents. When asked about perception of domestic and foreign food quality, a higher confidence in domestic products was confirmed, whereas Poland, China and Germany are considered as the most problematic countries in terms of food quality (Czech Agriculture and Food Inspection Authority [online], 2016). Preference of domestic products over foreign ones was confirmed also by other researches (Velčovská a Del Chiappa, 2015; Baker and Ballington, 2002).

### **1.2 Generation Baby Boomers**

Although marketers are currently focusing mainly on younger consumer groups (e.g. Millennials), the Baby Boomers segment is becoming into the center of attention in many EU countries. The Baby Boomers (also called Me Generation, Baboo, Love Generation, Woodstock Generation, Happy Generation) were born during 1946 – 1964. They represent a cohort that is significant on its size, accounting for 26 % of the total workforce in the Czech Republic (Manpower Group Solutions [online], 2016).

Baby Boomers are focused on using their free time for their hobbies, sports, cultural activities and education (Vysekalová et al., 2011). Family and health are very important values to them. They look for natural and organic foods and they like things that are relevant and appropriate to their life stage, not age (Stewart [online], 2009). While the group may be aging, Baby Boomers do not want to be reminded of that fact (Wong [online], 2010). Regarding marketing to the Baby Boomers segment, they are brand loyal and less price sensitive if they believe they are getting a superior product and good value (Wong [online], 2010). With their age, preferences of domestic products and brands are increasing (Vysekalová et al., 2011). In terms of communication, Baby Boomers like information presented in simple facts with which to make decision. It is effective to use word-of-mouth communications from trusted advisors and friends. They are heavy consumers of television programming, they use Internet search engines, e-mail, they watch online videos about products and services, and they also occasionally make online purchases. Baby Boomers are also active on social networks, especially on Facebook, where they like to publish news and photographs of their grandchildren or from their last vacation (Coates [online], 2017).

## 2. Problem Formulation and Methodology

With respect to above-mentioned significance of the Baby Boomers segment and a higher interest of consumers in product origin, the main objective of the research was to identify the Baby Boomers attitudes to food product origin in the context of product quality. Data were collected in April and May 2016 in online and personal survey via the structured questionnaire. Adding a personal survey was necessary from the reason that some older respondents had a problem with filling the online questionnaire. Generation Baby Boomers individuals with at least a partial responsibility for family food purchases (recruited with filtering question) served as a population for the survey. The respondents were selected by quota sampling with respect to the role of women and men in household food purchases. In accordance with the results of KPMG study from 2016, women (79.6 %) prevailed over men (20.4 %) in the sample of respondents. The reason lies in the fact that regular purchases of food are made mainly by women (KPMG [online], 2016). A total of 206 respondents completed the questionnaire, their structure is presented in Table 1.

**Table 1: Structure of Respondents (%)**

Variable		%	Variable		%
Gender	men	20.4	Responsibility for food purchases	full	79.6
	women	79.6		partial	20.4
Education	bellow secondary	14.6	Socio-economic status	self-employed	10.7
	secondary	36.9		employee	41.7
	university	48.5		pensioner	47.6

*Note: Due to the same share of gender structure and structure based on responsibility for food purchases, chi-square test was applied to find if there is any clue between these characteristics. The relationship was confirmed, Sig. = 0.000, Cramer's V = 0.282. Full responsibility for family food purchases is typical for women (85.4 % of women vs. 57.1 % of men).*

Source: Own processing based on data from IBM SPSS Statistics 23.0

The IBM SPSS Statistics 23.0 and Microsoft Excel software were used for data analysis. Pearson Chi-square test at 0.05 significance level was applied to test the differences between variables. The hypothesis  $H_0$  for Chi-square test presumes no statistically significant differences among variables, the hypothesis  $H_1$  presumes dependency of variables. Cramer's V coefficients were counted to prove the strength of relationship between variables. These descriptors were used to interpret the coefficients: 0.00 and under 0.10 - negligible association, 0.10 and under 0.20 - weak association, 0.20 and under 0.40 - moderate association, 0.40 and under 0.60 - relatively strong association, 0.60 and under 0.80 - strong association, 0.80 and under 1.00 - very strong association (Rea and Parker, 2014).

## 3. Problem Solution

The results are structured into four sections: (1) food quality indicators, (2) attention given to the product origin, (3) preference of product origin and perception of Czech and foreign food quality, and (4) the EU countries associated with high-quality and low-quality food products.

### 3.1 Indicators of Food Quality

The first part of the study was aimed at identification of attributes associated by respondents with the term "food quality". Specifically, the role of product origin in domestic country was

analysed. Respondents could indicate up to three factors from the list shown. The results are presented in Table 2. Food quality is mostly associated with product made from natural ingredients, followed by product beneficial to health. One third of Baby Boomers have food quality associated with product originated from domestic country.

**Table 2: Associations with the Term “Food Quality“ (%)**

Associations	%
food product made from natural ingredients	70.9
food product beneficial to health	36.9
product originated from domestic country	34.0
fresh food product	32.0
nutritionally balanced food product	28.2
food product certified with quality label	21.4
food product under known brand/manufacturer	16.5

Source: Own processing based on data from IBM SPSS Statistics 23.0

Respondents were also asked how they recognize a high-quality food when shopping. They can choose two main indicators of quality from the list shown or complete their own factor. The quality food is identified mainly based on consumer previous experience (55.3 %) and information about product ingredients (46.6 %) on the packaging. Among Baby Boomers is 13.6 % respondents who use quality labels to recognize the product quality. Only 8.7 % use the country of product origin as the main indicator of product quality in the place of purchase.

### ***3.2 Attention Given to Product Origin During Purchases***

The product origin is searched regularly by 63.1 % of Czech Baby Boomers (46.6 % mostly and 16.5 % always), sometimes by 28.2 %, exceptionally by 6.8 % and never by 1.9 % of them. In comparison with previous research studies presented in the Chapter 1.1, Czech Baby Boomers are less interested in the geographical origin of food than Europeans aged 55+ (European Commission [online], 2012), but they pay more attention to food product origin than average Czech population 18+ (Czech Agriculture and Food Inspection Authority [online], 2016).

The results were analysed based on socio-demographic characteristics of respondents. The relation between attention given to product origin and respondents' responsibility for food purchases was confirmed, Sig. = 0.035. Cramer's V coefficient (= 0.224) indicates a moderate association between variables. More attention to product origin is paid by consumers with full responsibility for food purchases, 68.3 % of them monitor the product origin mostly (50.0 %) or always (18.3 %), in comparison with 42.8 % of respondents with partial responsibility for food purchases (33.3 % mostly and 9.5 % always check product origin when shopping).

### ***3.3 Preference of Product Origin and Perception of Czech and Foreign Food Quality***

Respondents were asked to express their food origin preferences. They could choose one of the following options: food from local/regional producers in the Czech Republic, food from the Czech Republic, food produced abroad. Czech Baby Boomers have a strong preference of products manufactured in the Czech Republic. Ninety-eight percent give priority to products from national (79.2 %), regional or local (18.8 %) producers, and only 2.0 % favor foreign food products. It would be interesting to know the reasons of strong patriotism of Czech Baby

Boomers, but this topic was not examined in the study. Probably, it could be because older people are looking at the world differently than e.g. Millennials or Generation Z. In their youth, there was not an enough consumer goods on the Czech market, they did not have opportunity to purchase foreign products and they could not travel. Baby Boomers are more conservative and less adaptive to changes. They want to hold on what they had. Preference of domestic products over foreign ones was confirmed also by other research studies (Velčovská a Del Chiappa, 2015; Czech Agriculture and Food Inspection Authority [online], 2016).

Another studies (Cristea, Capatina and Stoenescu, 2015; Kalicharan, 2014; Diamantopoulos et al., 2011; Phau, Wang and Yang, 2008) have shown that the country of product origin has an influence on the perception of product quality. Therefore, it was examined how Czech Baby Boomers perceive the quality of Czech food products in comparison with foreign ones. As results show, the perception of domestic and foreign food quality is ambiguous and according to respondents' opinion, different from country to country. Almost half of respondents (44.6 %) answered that food quality depends on a particular country where the food product was produced. One third (30.7 %) consider Czech products as good as foreign. Domestic products are perceived as having a higher quality than the foreign ones by 21.8 % Baby Boomers, on the other hand, the opposite attitude (i.e. foreign product are a higher quality) have only 3.0 % of respondents (Table 3).

According to results of Chi-square test, perception of food quality depends on respondents' responsibility for family food purchases (Sig. = 0.020, Cramer's V = 0.220), education (Sig. = 0.023, Cramer's V = 0.190), socio-economic status (Sig. = 0.001, Cramer's V = 0.233), and preference of food product origin (Sig. = 0.000, Cramer's V = 0.332). Cramer's V coefficients indicate weak or moderate associations between variables. The most convinced of the quality of domestic products are respondents with partial responsibility for food purchases (35.0 %), with bellow secondary education (40.0 %), with preference of domestic products over the foreign ones (26.3 %), and pensioners (29.8 %).

**Table 3: Perception of Czech and Foreign Food Quality (%)**

		Czech products are a higher quality.	Czech products are as good as foreign.	Foreign products are a higher quality.	It depends on the particular country.
Total		21.8	44.6	3.0	30.7
Responsibility for food purchases	full	18.5	43.2	3.7	34.6
	partial	35.0	50.0	0.0	15.0
Education	bellow sec.	40.0	53.3	0.0	6.7
	secondary	21.6	40.5	2.7	35.1
	university	16.3	44.9	4.1	34.7
Socio-economic status	self-empl.	0.0	45.5	9.1	45.5
	employee	18.6	41.9	0.0	39.5
	pensioner	29.8	46.8	4,3	19.1
Preference of food product origin	local, reg.	5.3	42.1	5.3	47.4
	domestic	26.3	45.0	1.3	27.5
	foreign	0.0	50.0	50.0	0.0

*Note: It should be noted that the country of origin preference can switch also from one product category to another. However, this factor was not the subject of investigation. The research study was focused on the overall category of food products, not on particular subcategories.*

Source: Own processing based on data from IBM SPSS Statistics 23.0

### **3.4 Countries of Associated with High-Quality and Low-Quality Food**

Following the topic, respondents named EU countries associated with high-quality and low-quality food products. Czech Baby Boomers believe in the quality of their domestic products the most, Czech Republic was mentioned by 44.2 % of respondents as the country with high-quality food. On the second position, respondents rank Germany (38.8 %). Among other countries associated with high-quality food are France (12.6 %), Switzerland (6.8 %), Austria (5.8 %), and Italy (5.9 %). On the contrary, Poland was mentioned the most often as the EU country with food of poor quality (62.1 %). Only 2.9 % of respondents have associated their own country, i.e. the Czech Republic, with food products of poor-quality.

## **4. Conclusion**

To summarize the findings, the Baby Boomers consumers prefer domestic, regional or local food products and believe in their quality. Most of them check the product origin during purchases, however they do not use the product origin as the main indicator of product quality in the place of purchase, they rely primarily on their previous experience and information on the composition and nutritional value of the product. In comparison with previous research studies, Czech Baby Boomers are less interested in the geographical origin of food products than average EU population aged 15+ as well as EU population aged 55+ (European Commission [online], 2012), but they pay more attention to food product origin than average Czech population 18+ (Czech Agriculture and Food Inspection Authority [online], 2016). Comparison between Baby Boomers in the CR and other EU countries cannot be done because of missing data connected to this age cohort in individual EU countries. Only the results related to population aged 15+ are available. Among these EU consumers, Czechs pay above-average attention to geographical origin of food products. In individual EU countries, food product origin is important for 47 % (the Netherlands) to 90 % (Greece) of consumers. The level of importance in the CR is 80 %, what ranks Czech consumers (together with Slovaks, Lithuanians and Finnish consumers) on the fifth position among EU member states, behind an Greek (90 %), Italian (89 %), Slovenian (81 %) and Hungarian (81 %) consumers (European Commission [online], 2012).

When focusing on food quality, almost one third of Czech Baby Boomers consider Czech products as good as foreign, one fifth perceive them as being a higher quality than the foreign ones. The Czech Republic was also mentioned most often as the country with high-quality food, followed by Germany and France, whereas Poland is perceived as the country with food of poor quality. A higher confidence in domestic products and distrust in food coming from Poland was confirmed also in the research study „Food and Czech consumer“ from 2015 (Czech Agriculture and Food Inspection Authority [online], 2016). On the contrary, the perception of Germany as the country with problematic food quality was not confirmed, Czech Baby Boomers perceive Germany as the country producing a high-quality food.

It can be concluded that the country of origin has potential to be a powerful attribute that can be used to gain competitive advantage. Czech food producers are recommended to include the product origin as a part of their marketing strategy and to highlight the quality of their local, regional or national products in promotion campaign. It is obviously necessary to provide consumers relevant, complete and accurate information in an understandable form, taking into account suitable media with respect to Generation Baby Boomers specifics.

It is necessary to consider some limitation of the research. The study was conducted in the Czech Republic with focus on Generation Baby Boomers only. It could be useful to conduct more extensive study and compare consumers' attitudes in more EU countries or to include

other consumer generations into the comparison. Cluster analysis could be used with the purpose to create a consumer typology based on consumer attitudes to food product origin. The future research could be also focused on identification of specific drivers of product origin. The importance of product origin depends on the product category, therefore this topic can be developed.

### **Abstract**

*The article deals with the process of evolution from the point of view of social sciences, whose key components are usually considered competition, sustainable development and quality of life. It is divided into three main parts. The first one focuses on assessing the relationship between regional competitiveness and sustainable development. In this context, the hypothesis is verified that in the long term, both concepts are merging. The next part discusses their interactions with the component of quality of life, including the irreplaceable role of integration processes as the basis of social movement. The final part describes the possibilities of conceptualizing the findings with an emphasis on improving the quality of the business and social environment and the evaluation of the effectiveness of the projects. In this context, the article closely follows to rethinking of the European Union's cohesion policy.*

**Keywords:** cohesion policy, competitiveness, integration, quality of life, sustainability,

**JEL Classification:** A13, Q56, R11, R58

### **1. Introduction**

Despite the current positive economic development, we should not forget that the recent global economic crisis has essentially weakened the belief that using mathematical models can reliably predict economic growth and other basic macroeconomic variables and subsequently formulate a consistent economic policy. In line with this, there is an increasing demand for such procedures that would allow a more accurate response to the new economic, social and environmental challenges generated by societal development. In the case of the European Union the main focus is on interdisciplinary innovations of cohesion policy taking into account the structural and spatial differentiation of national or transnational systems. These innovations should focus on the key processes of societal evolution, the driving force of which is competition, the optimal direction is sustainable development and the main purpose being to improve the quality of life. In this context, it is about application of five fundamental principles.

- The principle of **holism** considers the systems as whole, not just as a collection of its parts. Its application opens the door to transition from neoclassical reductionist approaches to complex approaches respecting the openness of societal systems.
- The principle of **integration** means horizontal and vertical interconnection of parts into higher units that mirror the hierarchical organization of social systems in respects to the political, entrepreneurial, and social preferences of the population.

- The principle of **sustainability** assessed from a complex perspective including the economic, social, and environmental dimension of development, with a specific emphasis on the dynamic balance of mutual relations.
- The principle of **general utility** refers to activities that respect the legitimate interests of public administration and other entities in increasing the long-term benefits resulting from the allocation of public resources.
- The principle of **effectiveness**, understood as optimizing the selection of public projects – to frequently confuse the concepts of efficiency and effectiveness P. Drucker (Drucker, 1993) states that "Efficiency is doing things right; effectiveness is doing the right things".

## 2. Evaluation of the Relationship Between Competitiveness and Sustainability of Development

The concept of competitiveness is primarily related to the business sphere. Its definition is not settled, and only its simplest variant "competitive company is the one that exists", signaling links to sustainable development, can be considered as generally acceptable. Even more controversial is the territorial application, where we would come to the conclusion that the competitiveness of the given territory corresponds to the sum of the relevant values for the local companies. This approach ignores the fact that in the event of its loss, firms are pushed out of the market, while states and regions "only" lose their position (in addition, there are no clear relations - for example, redundancies of employees in order to maintain the competitiveness of firms have negative impacts on standard of living). Territorial competitiveness is defined particularly at a country level, while the competitiveness of regions is relatively rarely defined - the following table lists the most common types of definitions.

**Table 1: Frequently Mentioned Regional Competitiveness Dimensions**

Source: Kruk (2017)

From many definitions of territorial competitiveness, we consider it appropriate to mention the EU definition, which states "the ability of (regions) to generate, while being exposed to external competition, relatively high income and employment levels" (European Commission, 1999). According to Storper, the competitiveness of a region is its ability to attract and retain firms with a stable or growing market share, ensuring a stable or rising standard of living for those who participate in it (Storper, 1997). Many definitions state that territorial competitiveness cannot be measured solely on the basis of economic performance, but should also take into account the relevant assets of the socio-economic environment. According to these definitions, competitiveness depends on the values of shareholders and customers and the financial strength that determines the negotiating ability in the competitive environment and the potential of people and technologies necessary to implement the required strategic changes. Competitiveness can only be sustained long-term if there is a dynamic balance between these factors (Feurer and Chaharbaghi, 1994). The well-known World Competitiveness Reports, published by IMD Lausanne since 1989, take into account the political, social, and cultural dimensions of competitiveness, as interpreted on the basis of sophisticated analysis of selected countries. On the other hand, the similarly respected microeconomic index of global competitiveness from the World Economic Forum does not take into account the importance of social and environmental factors (this approach reflects significant methodological and technical difficulties associated with their measurement). In general, competitiveness measurement allows us to assess its partial aspects and provide to the public and private sphere selected information about the development trends of individual countries or regions. In this context, it is worth highlighting the growing consensus on the benefits of a holistic approach to multi-criteria index creation (see, e.g., Honová, Hon, 2014).

Regarding the relationship between territorial competitiveness and sustainability of development, we consider the crucial question of verifying the hypothesis that in the long-term period the concepts of competitiveness and sustainability are basically considered analogous. In this context, however, we are dealing with a significant problem of the vagueness of the relevant definitions - an example of this is the oldest definition of sustainable development by G. Brundtland, interpreting it as "a development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (World Commission on Environment and Development, 1987). For the macroeconomic analysis of the relationship between the relative amount of income and the quality of the environment, the Kuznets curve is often used to show the significant increase of environmental pollution in the initial phase of the economic growth, but after reaching a certain level of per capita income there is a positive turnaround of this trend (Kuznets, 1955). The followers of Kuznets demonstrate this hypothesis with the argument that with increasing income per capita people will voluntarily take better care of the environment. Though this behavior was not unambiguously confirmed, there are a number of examples that show this hypothesis could work in practice. For example, when income in the US in the 1960s increased considerably, people began taking a number of steps to reduce water and air pollution. On the other hand, rising incomes per capita in China or India do not point to a clear approach for a strategy for improving the environment (Rogers et al., 2008). It can be noted that due to market transformation, a number of environmental problems have been pushed into the background in the Czech Republic (Viturka, Vystoupil, 2017). Despite the increasing importance attributed to the relationship between competitiveness and sustainability, no generally acceptable model has yet been established. It is clear that the achievement of fundamental progress in the complex analysis of a given relationship is likely to be expected in a more distant perspective due to the diversity of stakeholder views and the enormous complexity of feedback and emerging synergies (Wilson, 2008).

### 3. Evaluation of the Relationships Between Competitiveness and Quality of Life

The comparative position of states and regions according to the level of social development can be understood as a cumulative result of long-term development of components of a competitiveness and quality of life. The definition of quality of life is also not unified; as logical it seems that it should reflect the degree of consistency between individual and social preferences (see e.g. Constanza et al., 2008). It is worth highlighting the increasing importance of quality of life for residential attractiveness, which together with investment attractiveness are the basic determinations of territorial development. The remaining component of sustainable development is in accordance with its universal nature to be integrated on the basis of a functional relationships within the two preceding components (social and natural systems are only partially compatible and the legislative protection of natural ecosystems is so irreplaceable). In this respect, costs and psychosomatic factors play a significant role.

The relationship between competitiveness and quality of life obviously depends on the level of development achieved, which takes into account the relevant changes in individual and social preferences. These changes have a strong impact on public expenses, whose priorities are gradually shifting from traditional support to development of production structures (such as technical infrastructure or investment incentives) to promoting sustainable development (e.g. education, health and social services). These questions were dealt with by the American Economist Porter, who formulated the four development stages of the competitiveness of countries (Porter, 1990):

1. competitiveness driven by the use of production factors,
2. competitiveness driven by investment,
3. competitiveness driven by innovation,
4. competitiveness driven by improving the quality of life.

For territorial quality assessments it is an appropriate sociological approach based on objective indicators of well-being reflecting the vision of desirable social development (Diener, Suh, 1997). At country level, the well-known Human Development Index published by the UNDP is based on three indicators: average life expectancy at birth, average length of education and GNP per capita. In other examples, SDG Index and Dashboard Reports focus on the assessment of the social and environmental component of development using the 17 indicator categories (Bertelsmann Stiftung and SDCN, 2017), and Global Liveability Ranking from The Economist Intelligence Unit. On the lower levels there is ranking of the quality of life of the world's metropolises, based on factors influencing the influx of talent and multinational companies. The index includes 39 indicators grouped into 10 basic categories: politics, economy, social environment, health, education, public services, leisure, consumer goods, housing and the natural environment. Another example of evaluation of quality of life in metropolitan regions is the Quality of Life Index, publishing by the Swiss Institute of BAK Economics. A total of 27 indicators are grouped into three basic categories (Pechlanger, Bachinger, 2010): economic environment (40%, e.g. hourly wage, tax burden, rent), social environment (40%, e.g. safety, standard of health services, supply of leisure time activities), and the environment (20%, e.g. number of rainy days, distance from the sea, public transport services). An interesting example is the Regional Quality of Living Index of Dutch research institute PBL, which integrates indicators of existing indexes and applies them at NUTS 2 level (Lagas, 2014). It is necessary to mention the multi-criteria evaluation of quality of life in Czech regions (Viturka et al., 2013). Its results show only slightly above-average dependence between the quality of the business and social environment, conditioned by the adverse effects of urban and environmental factors. In general, the interest in researching these issues is

increasing in the world and to a certain extent also in the Czech Republic (see, for example, Anders, Withey, 2012 or Fojtíková, Staničková, Melecký, 2016).

#### 4. Regional Conceptualization of the Examined Components

This conceptualization should be based on an in-depth analysis of the possibilities of competitiveness support, where golden rules defined by IMD can be used (Garelli, 2006; Margan, 2012):

- create a stable and predictable legislative environment,
- work on a flexible and strong economic structure,
- invest in traditional and technological infrastructure,
- support private savings and domestic investments,
- develop attractiveness for foreign direct investment,
- focus on the quality, speed, and transparency of government and administration,
- harmonize the relationships between wage levels, productivity and taxation,
- shape the social system by reducing income gaps,
- invest in education, including lifelong learning,
- maintain a balance between local and global economies.

Subsequently, the rules of the support of quality of life were formulated, which are oriented towards the European Union and optimized on the conditions of the Czech Republic:

- create a legislative environment ensuring the equality of citizens before the law,
- develop cooperation between the public and private spheres,
- care for the environment, and the natural and cultural heritage,
- stimulate the development of urban networks,
- improve social inclusion tools,
- strengthen the motivation tools, self-sufficiency, and tax powers of municipalities,
- increase the residential attractiveness of municipalities for current and potential residents,
- optimize territorial systems of education, health, and social services,
- support the development of civic activities,
- reduce the incidence of pathological phenomena.

When developing regional development concepts, it is appropriate to base around the territorial quality assessment of the business and social environments, which have strong links to the urban structure as the most stable components of social systems (see, e.g., Viturka et al., 2013). In the case of EU Member States, these concepts should also take into account the results of current discussions on perspectives of EU cohesion policy (European Union, 2017). In this context, we consider two issues of particular importance. The first concerns economic and social changes induced by globalization and political integration that objectively increases the importance of transnational and regional levels involvement in decision-making processes. The acute need for adequate responses to these changes has stimulated the usage of a system of pole and axes of development as the most significant concentration of socio-economic activities with the greatest potential for response and innovation as the leading factor of progress, which is not only a matter for individual companies (Žitek, Klímová, 2016). In this context, however, there is a strengthening of centralized management functions into the main metropolises, which leads to changes in the position of the regions, and thus to the rise of new divergent tendencies (see Viturka et al., 2017). These tendencies can be regulated, to a certain extent, through integrated strategies that support the dissemination of knowledge and the centrifugal reallocation of traditional industries. The overall outcome of the processes described above is the creation of ever more complexly structured regions with mostly positive

impacts on the cohesion of social systems. From the point of view of the Czech Republic, it is worth it to assign the importance of renewing traditional developmental axes connecting Prague with the most important metropolises of the neighboring countries. We also consider the quality of the institutional environment as one of the most important factor of public administration performance, which significantly influences the long-term success of the implementation of development concepts and projects. This conclusion is consistent with the fact that the lowest level of public administration in the EU concerns the least developed regions – in the Czech Republic it is primarily NUTS 2 Northwest (European Union, 2017).

Under the conditions of deepening globalization, the need for multi-criteria evaluation of the potential benefits of both public, and private projects in the spirit of principle "think globally, act locally" is logically increasing. Especially in the public sector, effectiveness comes more to the fore as part of the well-known concept 3E (effectiveness, economy, effectivity). Mainly due to the limited possibilities of monetary formulation, the multi-criteria evaluation of the effectiveness of large investment projects should be based on non-monetary criteria (e.g. relevance, usefulness, integration, stimulation and sustainability in the case of liner constructions). It is worth stressing that inappropriate project selection only on a CBA basis, cannot be offset by its effective implementation, and the assessment of its effectiveness can be considered as necessary part of the pre-investment phase (Víturka, Pařil, 2015).

## 5. Conclusion

The future of countries and regions is to optimally combine the main components of societal development with an emphasis on a consistent economic policy and integration strategies aimed at the overall improvement of its qualitative parameters. In line with changes in the ideological understanding of quality of life in democratic countries, the relationship between economic development and environment is becoming less confrontational and more complementary. This approach takes into account the importance of diverse feedbacks for the successful development of societal systems. In this context, it is necessary to mention strategic reflections of the future shape of EU cohesion policy, in particular the question of how much money should be allocated outside the less developed regions in order to achieve a higher aggregate level of added value. From a general point of view, it is clear that in order to realize the visions and strategies outlined above, there must be changes in the overall concept of public administration with an emphasis on integration of government policies. In this context, it is necessary to mention the ESPON program, which aims to support territorial cooperation between the EU countries in order to promote the dissemination of knowledge between public authorities and other actors at all hierarchical levels and thus contribute to the achievement of the objectives of cohesion policy.

### Abstract

*Economic convergence is a much discussed issue in the research community for a long time. It is much analyzed in the context of the integration of the economies in the European Union (EU) due to its importance in increasing cohesion among the member states and thereby strengthening the EU.  $\beta$ - and  $\sigma$ -convergence are two mostly used metrics in this regard. Such metrics investigate the convergence among all the economies under consideration. However, to analyze the growth of a specific economy, a metric with a more in detail investigation capability is expected. In this paper, we propose catching-up  $\beta$  ( $c\beta$ ) metric. The proposed metric can provide with more information regarding the growth of a specific economy that might help in making monetary decisions.*

**Keywords:**  $\beta$ -convergence, convergence, european integration, individual convergence, steady state

**JEL Classification:** C10, C20, C50

## 1. Introduction – Background of Economic Convergence

In economics, there are many theories and practices for measuring economic performances of different countries or regions. For analyzing the performances of the unions or integrations of different economies, such as European Union (EU), convergence is a much studied hypothesis. Upon the economic and monetary union of EU, the study and analysis of convergence among the economies of the EU countries has attracted many researchers (Brada and Kutan, 2001; Dvoroková, 2014; Gomez, 2008; Haviernikova, 2014; Soukiazis and Castro, 2005; Staničková, 2012; Taylor, 1999). The economists have primarily divided the analysis the convergence into two categories: nominal convergence and real convergence (Dvoroková and Hodula, 2014). In this paper, we focus on real convergence.

Traditionally, the real convergence is regarded as a decrease of economic differences among different regions or countries (Melecký, 2012). In the process of convergence, lower-income economies are expected to catch up with the higher-income economies in terms of different measures for economic condition, such as GDP per capita (ECB, 2015; Sala-I-Martin, 1996). Mathematically, the process is viewed as

$$\frac{y_{t_1}^a}{y_{t_1}^b} < \frac{y_{t_2}^a}{y_{t_2}^b}, \quad (1)$$

where  $a$  and  $b$  are lower- and higher-income economies, respectively,  $y$  represents per capita income of an economy at a given time, and  $t_1$  and  $t_2$  are the initial time and a later time, respectively, when the incomes are calculated.

## 2. Economic Convergence Metrics

Beta ( $\beta$ )-convergence and sigma ( $\sigma$ )-convergence are two popularly used concepts for the measurement of convergence. The  $\beta$ -convergence happens when lower-income economies follow the *catching up* process to grow more rapidly than the higher-income ones. On the other hand, the  $\sigma$ -convergence denotes lessening the dispersion of the levels of incomes of different economies.

For the  $\beta$ -convergence (Pfaffermayr, 2009), the growths of GDP per capita the economies in a time period are plotted against the GDP per capita the economies at the beginning of the time period, and a regression line as equation 2 is fit to the points on the plot.

$$\frac{1}{T} \log \left( \frac{y_0^i}{y_T^i} \right) = \alpha + \beta \log(y_0^i) + \gamma Z_i + \varepsilon_i, \quad (2)$$

where the equation's left part is the average of per capita GDP growth of country/economy  $i$  during time period from 0 to  $T$ ,  $y_j^i$  is the economic level of  $i$  at time  $j$ , and  $Z_i$  represents exogenous factors,  $\alpha$  is the level constant,  $\varepsilon_i$  is a random component, and  $\beta$  and  $\gamma$  are coefficients. When the value of  $\beta$  is negative for a group of economies, it indicates the existence of convergence phenomenon in them. The  $\beta$ -convergence basically refers to the faster convergence of the countries which have not yet reached their steady-states.

$\sigma$ -convergence indicates whether the dissimilarities among the economic levels of different countries or regions are decreasing over time, i.e., the presence of the catching up effect (Lucke, 2008).  $\sigma$ -convergence can be mathematically written as

$$\sigma_{t_1}^2 > \sigma_{t_2}^2, \quad (3)$$

where  $t_1$  is the initial time of a considered time period,  $t_2$  is the end of the period, and  $\sigma_t^2$  is the variance of the logarithm of the GDP per capita in the countries under consideration at time  $t$ .

## 3. The Proposed Metric

Both the  $\sigma$ - and  $\beta$ -divergence can be caused due to the low growth of smaller economies and/or high growth of larger economies. However, the aim of forming a union of some economies, such as EU, is at the growth of the economies. Hence, growth of larger economies should also be welcomed. Therefore, the main focus can be put on the low-growth of the smaller economies to ensure the overall growth of the union.

Again, traditional  $\sigma$ - and  $\beta$ -convergence focuses on the growth rates of the economies on a target time period. Hence, it shows the situation/condition of the economies in that particular time period. It does not speak about the trends of growths. In some situations, despite satisfactory growths of the smaller economies in a particular time period, a slower convergence may be observed due to the high growth of the larger economies. On the other hand, a  $\beta$ -convergence may still be observed even if the growths of all the economies decrease. Such a convergence, of course, is not expected, but the traditional  $\beta$ -convergence does not reflect such situations differently.

In this work, we propose a metric, *catching-up  $\beta$  ( $c\beta$ )*, which tries to reflect the trend of growth of the economies focusing on  $\beta$ -convergence. We follow the regression line on plot for testing

$\beta$ -convergence (Figure 1 shows such a plot). The economies falling under the regression line are actually having lower growth than what is expected in comparison with other economies under consideration. With respect to the current time period, the  $c\beta$  metric mainly focuses on the growth of these economies in the next time period.

**Figure 1:  $\beta$ -convergence in EU 2001-2012; ( $\beta = -0.027$ )**

Source: Authors’ calculations (Dvoroková, 2014)

A value for  $s_k^{t_p}$  is shown by the hollow circle on the x-axis, and the corresponding  $l_{g_{kt_p}}$  point is shown by the solid circle on the regression line  $L$ .

Let us suppose  $n$  economies  $e_0, e_1, \dots, e_n$ , where the sizes of the economies (in per capita GDP or logarithm of GDP, for example) are  $s_0^{t_p}, s_1^{t_p}, \dots, s_n^{t_p}$  at the beginning of a time period  $t_p$ , and the average growth rates of the economies during  $t_p$  are  $g_0^{t_p}, g_1^{t_p}, \dots, g_n^{t_p}$ , respectively. If the growth rates are plotted with respect to the sizes of economies, we will have a plot similar to what is shown in Figure 1.  $L$  is the approximated regression line.

Let us use the notation  $l_{g_{kt_p}} = L(s_k^{t_p})$  to represent the expected convergence point for the economy  $e_k$  to be on the convergence line. When  $l_{g_{kt_o}} = g_k^{t_p}$ , the growth of economy  $e_k$  can be thought to be in harmony with the  $\beta$ -convergence phenomenon observed in the concerned union of economies while  $l_{g_{kt_o}} < g_k^{t_p}$  indicates more growth of  $e_k$  than the required value to be on the regression line. On the other hand,  $l_{g_{kt_o}} > g_k^{t_p}$  means the growth of the economy  $e_k$  is less than what is the expected to ensure  $\beta$ -convergence. Accordingly, the  $n$  economies can be divided into two sets  $U_{t_p}$  and  $O_{t_p}$  as

$$U_{t_p} = \{e_k | l_{g_{kt_p}} > g_k^{t_p} \text{ and } k = 1, 2, \dots, n\}, \tag{4}$$

$$S_{t_p} = \{e_k | l_{g_{kt_p}} \leq g_k^{t_p} \text{ and } k = 1, 2, \dots, n\}. \tag{5}$$

Here the  $U_{t_p}$  is the set of the *undergrown* economies which are lagging to catch up with the  $\beta$ -convergence, while  $S_{t_p}$  can be thought to be set of the economies with comparatively *satisfactory* growth as the union of the  $n$  economies are concerned.

The proposed  $c\beta$  metric mainly focuses on the growth of the economies in  $U_{t_p}$ . Again, as mentioned earlier, we propose to track the growth rates in the next time period  $t_{p+1}$  too. Hence, we find the *undergrowing* economies  $U_{t_p}^N$  as

$$U_{t_p}^N = \{e_k | l_{g_{kt_p}} > g_k^{t_{p+1}} \text{ and } k = 1, 2, \dots, n\}. \tag{6}$$

$U_{t_p}^N$  consists of the economies having less growth in the time period  $t_{p+1}$  than what is required to be on/above the regression line drawn for the time period  $t_p$ . Such economies may include some of the economies in  $U_{t_p}$  who are still under the regression line and some others who are not maintaining their growth in  $t_p$  in the next time period.

Upon finding the sets  $U_{t_p}$  and  $U_{t_p}^N$ , our next concern is to quantify the laggings of these economies to catch up with regression line. For the time period  $t_p$ , we calculate the value as

$$d_{kt_p} = g_k^{t_p} - l_{g_{kt_p}} \tag{7}$$

Clearly, the economies in  $U_{t_p}$  will have negative  $d_{kt_p}$  values while the  $d_{kt_p}$  values calculated for the economies in  $U_{t_p}^N \setminus U_{t_p}$  will be positive.

Similarly, we propose to follow the laggings of these economies in the time period  $t_{p+1}$  with respect to the regression line for  $t_p$  as

$$d_{kt_p}^N = g_k^{t_{p+1}} - l_{g_{kt_p}} \tag{8}$$

Note that all the economies in  $U_{t_p} \cup U_{t_p}^N$  will have negative  $d_{kt_p}^N$  values.

$d_{kt_p}$  quantifies the required *catch-up growth* for  $e_k$  to be on the regression line to maintain the  $\beta$ -convergence during  $t_p$  while  $d_{kt_p}^N$  provides with the *catch-up growth* that is still required in the next time period with respect to the same reference level.

Based on  $d_{kt_p}$  and  $d_{kt_p}^N$ , the proposed *catching-up*  $\beta$  ( $c\beta$ ) metric quantifies the advancement of the economy  $e_k$  made in the next time period as

$$c\beta_k^{t_p} = \begin{cases} d_{kt_p}^N - d_{kt_p} & \text{if } e_k \in U_{t_p} \cup U_{t_p}^N \\ \infty & \text{otherwise} \end{cases} \tag{6}$$

A positive value of  $c\beta_k^{t_p}$  indicates the advancement in growth of the economy while a negative value indicates worsening.

#### 4. Discussion

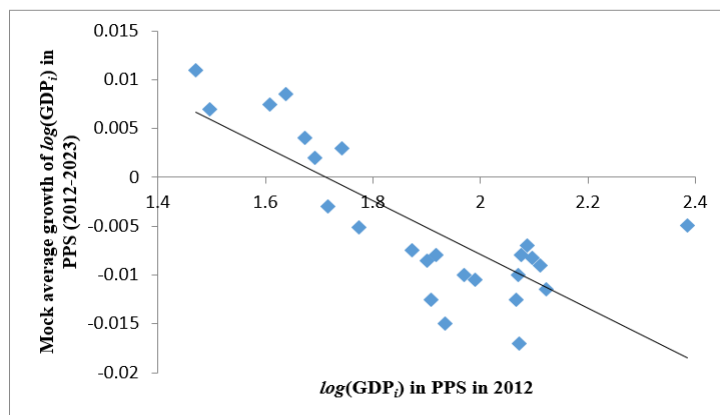

While  $\beta$ -convergence provides with an overall idea about the conditions of convergence of the economies under consideration, it does not clearly show the performances of the economies individually so that policy makers can rigorously analyze the economies to take monetary decisions in order to improve their situations. On the other hand, the proposed  $c\beta$  metric provides with the individual performances of the different economies under consideration. Hence, it has the potential to help the policy makers to take necessary steps to strengthen their productivity growths through revising the fiscal policies and structural set-ups to ensure more favorable conditions for making better utilizations of available resources in the economies.

Another interesting point about  $\beta$  (and also  $\sigma$ )-convergence is that it performs a relative measurement among the different economies. Such a convergence may not necessarily happen

as a result of economic developments. For the sake of analysis, let us suppose that each of the average growth rates of the countries during 2012-2023 is 0.01 less than what is reported in the Figure 1. This leads us to Figure 2. Interestingly, we get almost the same  $\beta$  value here as well. Thus for both the data in Figures 1 and 2,  $\beta$ -convergence reports the same convergence phenomenon though growth rates are much different. The  $c\beta$  values calculated in the two time periods will be negative for every country, indicating the unexpected decrease of the economic growth.

**Figure 2:  $\beta$ -convergence in Synthetic/Mock Data of EU 2012-2023; ( $\beta = -0.0272$ )**

Source: Data in  $x$ -axis are authors' calculation, and each of the data in  $y$ -axis are 0.01 less than what is reported in Figure 1.

For a sustainable convergence, the growths of the lower income economies are also required to be sustainable (ECB, 2015). In other words, a consistent long-term growth is necessary. However, the traditional  $\beta$ - and  $\sigma$ -convergences present the information of overall conditions of the economies. Since such calculations are done on the data at the start and end of a specific duration, they do not provide mechanisms to investigate the ups and downs that might happen in between. At this point, the duration can be divided into smaller time periods, and the  $c\beta$  values can be calculated at all these time periods. This will give much better insights about the actual growth of the economies.

## 5. Conclusion

We have proposed the  $c\beta$  metric as a supportive measure to enable detail analysis of performances of different economies. While the traditional  $\beta$ - and  $\sigma$ -convergences focuses on the overall relative growth of all the countries under consideration, the proposed metric shows a way to look into more detail of the growths of the countries' economies, analyze the trends of the growths and thereby take necessary actions.

In this paper, we have mainly focused on the theoretical concept of the proposed metric. We look forward to make a practical study using this metric to analyze the economies of the countries in EU in our next work. Again, we have put the principle focus on the economies falling under the regression line. However, the proposed  $c\beta$  metric can also be used to analyze the other comparatively *better-performing* economies as well. A way to perform comparative analyses may also be possible based on the  $c\beta$  values of different economies. We leave these here as our future endeavor.

## **Abstract**

*The negative consequences of the rapid passengers and cargo air transport development, such as climate change and the increase in air pollutants emissions, caused the tightening of the EU climate policy towards the aviation sector. One of the actions taken by the EU to reduce CO<sub>2</sub> emissions derived from commercial flights was the inclusion of aviation into the European Union Emission Trading Scheme (EU ETS). The paper presents the most important rules of the EU climate policy aimed at the CO<sub>2</sub> emissions reduction by aircraft operators, mainly related to their participation in the EU ETS. The changing EU climate policy is a source of uncertainty about future operating conditions for aviation sector companies, which may also affect investors' interest in this sector. Therefore, the Markov-switching multifactor model is used to assess the impact of the European Aviation Allowances prices' variability on the market value of chosen European aviation companies in the period 2012-2017.*

**Keywords:** aviation sector, CO<sub>2</sub> emissions, emissions trading, EU climate policy

## **1. Introduction**

The dynamic development of passenger air transport in last decades constitutes a vital element of the ongoing globalization process, and also a factor that stimulates social and economic development (Mesjasz-Lech, 2016; Simarmata et al., 2017). According to the Airports Council International, passenger traffic will be increasing at the predicted growth rate of 4.9% per annum in 2015-2040. It is worth stressing that this growth rate will lead to double of global passenger traffic to over 14 billion by 2029 (ACI WATF 2016). The abovementioned statistics should be also analysed in the context of negative influence of air transport on the natural environment, in particular emission of toxic exhaust gases that are directly or indirectly a threat to human health. Air pollutants emission depends to a large extent on the aviation fuel quality and the process of its combustion in aircraft engines. For this reason, the EU policy stresses both a larger utilization of bio-fuels in the aviation sector as well as low-emission improvement of aircraft engines that is connected with lower fuel consumption while preserving the safety of aircraft construction (Skrodzka, 2016). In the years 1990-2005 a growth in the emission of CO<sub>2</sub> was recorded in the aviation sector from 88 to 156 million of tonnes, thus, in 2005 the emission of carbon dioxide coming from fuel combustion while carrying out flights grew by 77% compared to 1990 (European Aviation Environmental Report, 2016). In order to assess the radiative forcing from aviation, it is needed to evaluate the whole carbon cycle in the environment pointing at the long lifetime of CO<sub>2</sub> (100 - 1000 years), without focusing only on short-lived aviation emissions (Dessens et al., 2014). Taking all these into account large hopes related to limiting air pollutants emission and stopping the anthropogenic climate changes that

accompany them are placed on the introduced on a global scale regulations on CO<sub>2</sub> emission in the aviation sector. Small progress achieved by the International Civil Aviation Organization (ICAO) in developing a global market based measure was one of the reasons of taking by the EU unilateral actions on tightening the climate policy towards civil aviation. This resulted in inclusion of civil aviation into the European Emission Trading Scheme at the beginning of January 2012 (Preston and Hooper, 2012).

With this reference the paper presents the most important principles of the EU climate policy aimed at limiting the CO<sub>2</sub> emission generated by civil aviation, which are connected with the EU ETS functioning. Tightening the EU climate policy and legislative changes that followed it are a source of uncertainty for aircraft operators with regard to future conditions of conducting air operations within the territory of the European Economic Area. They can also contribute to a lower investor interest in this sector. For this reason, the goal of the paper is to evaluate the influence of the EU ETS on the market value of selected European airlines in the period from 2012 to 2017, which was characterized not only by the changes in the principles of aviation functioning in the EU system, but also finalizing the works of ICAO on the Carbon Offsetting and Reduction Scheme for International Aviation (CORSIA). The Author has constructed the Markov-switching multifactor model with GARCH structure, on the basis of which the significance of CO<sub>2</sub> emission allowances market price impact on prices of shares of analysed airlines has been verified depending on the valid volatility regime. The identified volatility regimes have been compared to periods when changes to the EU climate policy and the EU ETS functioning were introduced, which concerned civil aviation.

## 2. The EU Policy of CO<sub>2</sub> Emission Reduction by Civil Aviation

Since 2012 aircraft operators performing flights within the territory of the European Economic Area have been obliged to monitor own CO<sub>2</sub> emission in each calendar year and account for it with the use of special emission allowances (the Directive of the European Parliament and of the Council 2008/101/WE). Aircraft operators may apply the following options while accounting for own CO<sub>2</sub> emission within the EU ETS scheme (Scheelhaase et al., 2018):

- covering the emission with allocated free of charge or purchased in the auctioning system European Union Aviation Allowances (EUAs), which are destined for the aviation sector exclusively;
- covering the emission with purchased on the secondary market European Union Allowances (EUAs), which are destined for other sectors included into the EU ETS;
- using permits from Kyoto-based „Clean Development Mechanism” (CERs) and “Joint Implementation” (ERUs) for up to 1.5 per cent of the number of allowances individually required for surrendering in a given year.

The most important principles concerning the size of the allowance pool destined for the aviation sector and principles of its allocation have been presented in Table 1.

The decision of the EU on including the aviation sector into the EU ETS has been widely discussed on the international fora, the most frequently mentioned issues have concerned additional cost imposed on aircraft operators from outside the EU. Environmental costs result from the necessity of annual monitoring, registering and accounting for own emission of greenhouse gases in the Union Registry, and thus aircraft operators have been burdened with administrative costs, cost of purchasing CO<sub>2</sub> emission allowances and introducing a system for managing them, and also costs that accompany new green investments in the aviation sector (Preston et al., 2012).

**Table 1: Allocation Principles of Aviation Allowances Pool in the Period 2012-2020**

Characteristics	Period of “learning how to function in the system”: 2012	Adequate period: 2013-2020
<b>„Cap” level</b>	It was set 3% below the mean average historical annual aviation emissions for the period of 2004 – 2006: 212 892 053 t of CO <sub>2</sub>	It was set 5% below the mean average historical annual aviation emissions for the period of 2004 – 2006: 208 502 526 t of CO <sub>2</sub> from 2013 onwards
<b>Allowances granted free of charge</b>	85%	82%
<b>Allowances to be sold in auctioning sales</b>	15%	15%
<b>Allowances moved to a special reserve</b>	-	2%

Source: own elaboration based on Preston et al. (2012), p. 51

With this reference, participants of the EU ETS scheme that represent civil aviation more and more often raised the issue of the distortion of the competitive equilibrium on the international and domestic flights market, which was the cause of starting the research concerning the impact of the EU ETS on the financial condition and competitiveness of airlines. It has been demonstrated, among others, that the influence of direct costs of participating in the EU ETS on the situation of Italian airline operators was limited. However, a growth of these costs importance has been forecast after 2016 due to the expected increase in CO<sub>2</sub> emission allowances price in the auctioning system, change of demand price elasticity and the possibility to pass on the majority of the costs related to participation in the EU ETS scheme on airline customers. Moreover, the compliance of the Directive 2008/101/WE with the Chicago Convention on International Civil Aviation (1944) was disputed on the international fora, where imposing additional financial burdens on air carriers from outside of the EU without prior consultations in this scope with all interested parties was questioned (Meleo et al., 2016). This resulted in intensified works of ICAO aimed at achieving an agreement concerning the construction and implementation of global market based measure (GMBM) to limit carbon dioxide emission in international aviation. The European Union’s reaction in this respect was suspending temporarily for the years 2013-2016 the implementation of the EU emission requirements for flights from and to airports located outside the European Economic Area. Additionally, flights between airports located in the EEA and most remote areas within the EEA were excluded from the scheme (Decision 2013/337/EU; Regulation 421/2014). Lack of progress in the works of ICAO would result in no changes introduced into the directive with regard to EU ETS, and this in turn would mean restoration of the EU ETS scheme full application since the beginning of 2017.

All these actions were summarized by concluding an agreement in Montreal (2016) that concerned implementation by governments of particular countries the Carbon Offset and Reduction Scheme for International Aviation (CORSIA). This measure is supposed to facilitate achievement of the goal, which is stabilizing the international aviation emission at the level from the year 2020 through the use of carbon offset scheme worldwide since 2021.

Continuing the support for IACO's actions to implement the global market based measure the EU decided to prolong for the whole of the 2017 the operation of derogation mechanism with respect to flights to and from airports outside of the EEA, according to the Regulation No 421/2014. Preparing itself to implement since 2021 the CORSIA scheme and having regard to the fact of controlling the CO<sub>2</sub> emission coming from flights between airports located within the EEA, the EU decided to prolong until 31 December 2023 functioning of aircraft operators in the EU ETS scheme under the current rules. Prolonging the operation of the derogation mechanism is also connected with proportional decrease in the amount of allowances destined to be sold at auctions and issued free of charge, including a special reserve, in order to avoid an occurrence of emission allowances oversupply on the secondary market. Moreover, since 2021 the pool of aviation allowances granted to aircraft operators will be decreasing annually according to a linear reduction coefficient, which is used in other sectors covered by the EU ETS scheme (Regulation of the European Parliament and of the Council 2392/2017).

### 3. Markov-Switching Multifactor Model with GARCH Structure

The calibration of the multifactor model proposed by Oberndorfer (2009) has been conducted, which consisted in rejecting the assumption that structural parameters are fixed values. A multifactor model with variable parameters that are generated by a random process allows for describing a non-linear nature of dependencies between market price of CO<sub>2</sub> emission allowances and value of European airlines shares. In particular this class of models allows to verify whether the increased volatility periods of airlines share prices correspond to the periods of introducing changes to the EU climate policy and periods of finalizing the works of ICAO on introducing the global market based measure. The following form of Markov-switching multifactor model with GARCH structure was estimated (Oberndorfer, 2009; Doornik, 2013):

$$r_t = \psi_0(s_t) + \psi_1(s_t)r_{m,t} + \psi_2(s_t)r_{CO,t} + \psi_3(s_t)r_{fuel,t} + \sum_{i=1}^p \varphi_i(s_t)r_{t-i} + \varepsilon_t \quad (1)$$

$$\varepsilon_t = \sigma_t(s_t) \cdot \xi_t \quad (2)$$

$$\sigma_t^2(s_t) = \omega(s_t) + \alpha_1(s_t)\varepsilon_{t-1}^2 + \beta_1(s_t)\sigma_{t-1}^2 \quad (3)$$

$$\xi_t | \Omega_{t-1} \sim N(0,1) \quad (4)$$

where:  $r_t$  – airline shares return in the period  $t$ ,  $r_{m,t}$  – market portfolio return,  $r_{CO,t}$  – percentage change of CO<sub>2</sub> emission allowances price,  $r_{fuel,t}$  – percentage change of crude oil price,  $\Omega_{t-1}$  – set of available information up to the moment  $t-1$ ,  $\psi_\kappa(s_t)$  ( $\kappa = 0, \dots, 3$ ) and  $\varphi_i(s_t)$  ( $i = 1, \dots, p$ ) – parameters dependent on the regime, autoregression order  $p$  determined on the basis of Akaike's Information Criterion (AIC),  $\varepsilon_t$  – random coefficient,  $\sigma_t(s_t)$  – conditional standard deviation of random coefficient dependent on regime,  $\alpha_1(s_t)$  – dependent on the regime ARCH structure parameter indicating the impact of information flowing to the market on volatility of airline shares price volatility,  $\beta_1(s_t)$  – dependent on the regime GARCH structure parameter proving the persistence of volatility process of airline shares price,  $\xi_t$  – independent random variables of standardized normal distribution.

The  $\psi_1(s_t)$  parameter shows the reaction of airline shares to changes of market portfolio,  $\psi_2(s_t)$  parameter is a measure of airline shares sensitivity to changes of CO<sub>2</sub> emission allowances, while the parameter  $\psi_3(s_t)$  indicates the reaction of airlines to changes of crude oil prices in particular regimes.

The changes of airline shares prices volatility regimes are controlled by a non-observable random variable  $s_t$ , which most frequently is a homogeneous Markov chain of transition probability matrix  $P$  (Hamilton, 1994):

$$P = \left[ p_{ij} \right]_{i,j \in \{0,1,\dots,N-1\}}, \quad (5)$$

the elements of which determine the process transition probability from the state  $j$  at the moment  $t-1$  to state  $i$  at the moment  $t$ .

Moreover, the elements of  $P$  matrix comply with the following conditions (Hamilton, 1994):

- Markov property

$$p_{ij} = P(s_t = i | s_{t-1} = j, s_{t-2} = i_{t-2}, \dots, s_1 = i_1) = P(s_t = i | s_{t-1} = j) \quad (6)$$

- conditions that guarantee the stochastic structure of  $P$  matrix

$$p_{ij} \geq 0 \quad \text{and} \quad \sum_{i=0}^{N-1} p_{ij} = 1 \quad \text{for } i, j = 0, 1, \dots, N-1. \quad (7)$$

Parameters of Markov-switching multifactor model with GARCH structure are estimated with the maximum likelihood method, in which the logarithm of likelihood function is maximized in the form (Doornik, 2013):

$$\ell(\theta) = \sum_{t=1}^T \ln \left[ \sum_{j=0}^{N-1} f(r_t | s_t = j, x_t, \Omega_{t-1}; \theta) \cdot P(s_t = j | \Omega_{t-1}; \theta) \right] \quad (8)$$

where:  $\theta$  – vector of estimated parameters.

The Feasible Sequential Quadratic Programming algorithm was used in the estimation process, with an additional option of searching for the global maximum of the likelihood function after one of the local maxima had been found. An additional estimation product is the smoothed probabilities sequence  $P(s_t = j | \Omega_t)$  ( $t = 1, 2, \dots, T$  and  $j = 0, 1, \dots, N-1$ ), which allow to assign each observation  $r_t$  to one of the volatility regimes.

#### 4. Assessment of the EU Climate Policy Impact on Airlines Shares Prices Based on Markov-Switching Model

In this paper the short-term relations occurring between the share prices of three large European airlines groups, namely Lufthansa Group, International Airlines Group (IAG), Air-France KLM and CO<sub>2</sub> emission allowances prices are analysed in the period from 04.03.2012 to 31.12.2017 (daily data). The choice of the research period is connected with the inclusion aviation into the EU ETS and introduction into trade the EUAA futures contracts by the Intercontinental Exchange Futures Europe in London (ICE Futures Europe) in February 2012. In order to obtain a benchmark series for both EUAA and EUA prices (EUR/tCO<sub>2</sub>e), the December futures contracts listed on the ICE Futures Europe are rolled over according to the "Delivery-day" criterion (Carchano et al., 2014). Two additional control variable (market portfolio and fuel prices) are included into this analysis in order to explain the influence of the "business climate" of given stock exchange and crude oil prices on the market value of aviation companies' shares. Market portfolio is described respectively by DAX, FTSE100, CAC40 indices, while fuel prices are represented by Brent crude oil prices (USD per barrel). In case of Lufthansa and Air France models, Brent crude oil prices are converted from US dollars to Euros using the USD-EUR exchange rate. In order to make the comparison between the IAG

price volatility and carbon permits, crude oil and market portfolio volatility, Brent crude oil prices and both the EUAA and the EUA prices are denominated in British pounds using the USD-GBP and EUR-GBP exchange rates. The data was retrieved from Stooq Financial Service (exchange rates, shares prices, stock exchange indices), the Energy Information Administration (Brent crude oil process) and Quandl database (EUAA and EUA futures prices). The analysis is performed on log returns of the prices and its preliminary stage concerns the verification of dynamic properties (stationarity, structural break occurrence, autocorrelation and volatility clustering effect) of each financial return series. The results of conducted diagnostic tests justify the use of Markov-switching multifactor model with GARCH structure (1)- (4) in the further analysis. Due to the presence of serial correlation in some return series the autocorrelation order is set up to four and number of possible volatility regimes is determined as two or three. Estimation results for the best models are presented in Table 2.

Source: own calculations.

Two regimes were distinguished in the course of modelling: the regime of normal volatility of airlines share prices (regime 1) and high volatility one (regime 0). In case of Air France and Lufthansa shares, one can notice that coefficients that illustrate the influence of capital market risk are statistically significant at 0.05 in each regime. In normal volatility regime all airlines' shares are defensive in relation to their market portfolio, which means that when the values of the CAC40, FTSE100 and DAX portfolios grow by 1% *ceteris paribus*, then the value of airlines shares will grow on average respectively by 0.8801% (Air France), 0.0885% (IAG) and 0.8952% (Lufthansa). In the high volatility regime in turn the drop of the CAC40 and DAX indices by 1% may contribute to the decrease in airlines' market capitalization on average respectively by 1.0494% (Air France) and by 1.1833% (Lufthansa). In the periods characterized by high volatility of airline share prices (regime 0), the direction of the influence of EUAs price changes on the returns of Air France, IAG and Lufthansa is negative, but statistically insignificant. It is worth stressing that the impact of changes of aviation allowances prices on three airlines group is statistically insignificant in each regime. This can be the result of low share of auctioned allowances in total allocated permits intended for covering of emissions from aviation activities (only 15%) and the possibility of environmental cost passing through to the passenger, as well as, the relatively loose reduction target referring to the international aviation. Moreover, the increase in crude oil prices significantly influences on the decrease in airlines share prices in normal volatility regime, but the reaction of airlines share prices on this factor is weaker compared to the reaction on changes in market portfolio values on the stock exchange. While comparing the unconditional variance in regime 0 to unconditional variance in regime 1, it can be observed that in case of IAG this ratio is the smallest, and for Lufthansa is the biggest as it is amount to more than five. Evaluating the estimated values of transition probabilities between regimes 0 and 1 it can be observed that the normal volatility regimes are stable in case of each airline. In turn, the high volatility regimes for Air France and Lufthansa are temporary regimes, which means that there is a great chance (respectively 0.7427 and 0.8826) that in the next period high volatility regime will be replaced by the normal one. Only single returns, which indicate at extreme changes of Air France or Lufthansa prices, have been assigned to high volatility regime. Therefore, this regime may be treated as "spiky" regime connected with the structural changes on analyzed markets or in the airline activities. It is worth stressing that for all Markov-switching multifactor models with GARCH structure, the Davies (1987) upperbound for the p-value of the LR test of linearity strongly rejects the linear model (Doornik, 2013).

On the basis of obtained in the estimation procedure values of smoothed probabilities the moment of process switching between particular volatility regimes were estimated (Fig. 1).

2017-12-13	Regulation 2392/2017 continuing the reduced scope referring to GHG emissions	-	-	2017-12-08 (0.966)

Note: smoothed probability assigning return to the high volatility regime in parentheses.

Source: own elaboration based on Official Journal of the European Union and Fan et al. (2017), p. 148

Next, the periods of high volatility identified on the basis of Markov switching model for each airline are compared to these regulatory policy adjustments events. Such approach enables to assessment whether the changes in the EU climate policy rules affected the volatility of market prices of chosen airlines.

The common periods assigned to the spiky volatility regime correspond with such events as:

- updating on both the benchmark to allocate carbon dioxide allowances free of charge and the aviation corporation list. These events determined the aviation cap and the coverage scope of the aviation trading system, as well as the possibility of the use another units in the covering emissions derived from international aviation;
- rejecting by the European Parliament in April 2013 the decision on back-loading, the aim of which was to partially solve the problem of surpluses of CO<sub>2</sub> emission allowances in the third stage of the EU ETS functioning. It had also a negative influence on aviation allowances prices;
- publishing both the decision of the European Parliament and Council on implementing the „stop the clock” mechanism and the Regulation 421/2014 on further derogation in aviation, that pointed to the continuation of the EU "Reduced Scope" regime. It was significant signal that the EU would track the progress in the ICAO work over the construction of the global market based measure;
- taking discussions on the further regulations referring to the narrowing the capped aviation activities within the European Economic Area (e.g. Commission's proposal concerning the applying the EU ETS to European regional airspace);
- conclusion of an global agreement regarding implementation of the Carbon Offset and Reduction Scheme for International Aviation and the continuation of the "Reduced scope" regime of the EU ETS in the EU climate policy.

These results are in line with the assessment of the impact of regulatory policy adjustments events on aircrafts operators activities made by Fan et al. (2017). Moreover, the implementation of the „stop the clock” mechanism caused the postponing the deadline to settle the emission from aviation operations within the EU ETS for 2013 and 2014, delayed the launch of aviation allowances trading in the auctioning system, what increased uncertainty of aircraft operators about the future development conditions. Therefore, the end of April in two subsequent years, being the deadline for each aircraft operator to settle own CO<sub>2</sub> emission for the previous years with the use of accumulated emission allowances, were also assigned to high volatility regime on the basis of Markov-switching multifactor models.

## 5. Conclusion

The paper pertains to the issue of the tightening of the EU climate policy rules referring to civil aviation sector under the expectation on the concluding the agreement concerning the construction and implementation of the global market based measure to limit carbon dioxide emission in international aviation by the ICAO. The analysis covers period from the inclusion of civil aviation into the EU ETS (2012) to publishing the official EU position on the continuation of current limitations of scope for aviation activities and preparing the implementation of the CORSIA scheme. Maintaining a limited scope of EU ETS application after the year 2016 was supposed to be a stimulus for further works on the international fora to develop detailed description of the CORSIA system. The above stance of the EU was also supported by scientific research that shows that best results in the scope of reducing the CO<sub>2</sub> emission generated by civil aviation would be possible to achieve if the two market based

measures operated simultaneously. This means maintaining the obligation to account for flights within the European Economic Area after the year 2020 within the EU ETS scheme and a simultaneous application of the CORSIA system with regard to flights into and from the EEA (Scheelhaase et al., 2018).

Decisions concerning tightening the EU climate policy in the scope of greenhouse gases emission while performing international aviation operations and modifying the principles of the EU ETS functioning will affect competitiveness of aircraft operators performing flights within the European Economic Area in the years 2012-2017 and may also contribute to a lower investor interest in this sector. In particular, market capitalization value of airlines companies may be sensitive on the market price of both EUAAs and EUAs, as well as the rapid changes in the carbon dioxide emission permits prices observed in the secondary market. The EUAA or EUA futures contracts have been designed in order to hedge aircraft operators against the unfavourable and rapid changes in the allowances prices. Therefore, Markov switching multifactor model with GARCH structure was estimated for three big airlines companies in order to evaluate the impact of changes in the CO<sub>2</sub> emission allowances prices on market capitalization of airlines across different volatility regimes. It was found that the impact of changes of aviation allowances prices on three airlines group was statistically insignificant in each regime. Moreover, common for all airlines extremely high volatility periods, which indicated at the increase in market risk associated with the airlines shares' investment and might decrease the market capitalization of given airline, were generated by the important changes in the EU climate law, especially concerning the reform of the EU ETS system.

### **Abstract**

*The European Union aims to maintain and develop an area of freedom, security and justice in which the free movement of persons is ensured. The increasing European integration and the growing mobility in the internal market inevitably result in an increase in the cross-border relationships, including international marriage and divorce. In this respect, divorce has not only personal, but also significant economic effects (i.e. effects on matrimonial property). Nevertheless, legal regulation varies throughout the EU Member States, which provides for uncertainty for the spouses. Moreover, this may lead to disadvantageous implications for the rights of third parties (especially creditors). In 2016, the EU adopted regulation to eliminate the obstacles to the free movement of persons, in particular the difficulties experienced by the international couples in dividing their property upon divorce. The aim of this paper is to analyse whether the newly adopted EU instrument provides for the effective and predictable solution of the economic consequences of divorce.*

**Keywords:** *cross-border relationships, economic consequences of divorce, EU regulation, free movement of persons, matrimonial property regimes*

**JEL Classification:** *K30, K33, K36*

### **1. Introduction**

“Freedom of movement of Union citizens is certainly one of the most successful achievements of European integration” (Maslowski, 2016, p. 594). Firstly, the free movement of economically active persons (workers, self-employed persons, and entrepreneurs) was covered. Afterwards, with the introduction of citizenship of the European Union (“EU”), the right of persons to move and reside freely within the territory of the EU Member States was extended to students, retired and other economically non-active persons as well (European Parliament [online], 2018; Sopková, 2004, pp. 328–329; more to the legal basis see Art. 3 para. 2 of the Treaty on European Union (“TEU”); Art. 21, Arts. 45 et seq., Arts. 67 et seq. of the Treaty on the Functioning of the European Union (“TFEU”).

The rise in mobility of persons within the European Union inevitably results in an increase in the cross-border legal relationships, in which the law of more than one EU Member State may apply (Van Erp, 2010, p. 6). The EU citizens are allowed to move freely across national borders to work, study or start a family in another Member State. It means that not only international commercial transactions, but also cross-border family relations become more and more common within the European single market. Consequently, there is a need for adoption of the appropriate legal instruments designed to handle the cross-border legal relationships and disputes (similarly Rozehnalová, 2013, pp. 17–18).

Accordingly, the number of international couples or couples having an international (cross-border) dimension is growing (European Commission [online], 2017). In 2015, marriages where at least one of the spouses was of different nationality to the country in which they reside accounted for 10.5 % of all marriages in the EU (Eurostat, People [online], 2018). In this paper, however, we are not only focusing on the spouses of different nationalities, but also couples living in an EU Member State other than that of their nationality, and couples who acquire property in more than one Member State (Viarengo, 2011, p. 200) (hereinafter referred to as “international couple” or “international marriage”).

Besides, we are also witnessing a rise in divorce rates as high number of marriages end in divorce. In this situation, the effects of divorce of marriage are of considerable importance (Siehr, 2012, p. 684). It should be emphasised that divorce may not only have an enormous impact on personal lives of the spouses, but also on their property relations – both between the spouses and in their relations with third parties, especially creditors (similarly Dvořák and Spáčil, 2011, p. 2). One of the most important economic consequences is the dissolution of matrimonial property, which is closely linked to the particular matrimonial property regime (Martiny, 2012, pp. 493, 495; see also Ribot, 2011, pp. 71–86).

Nevertheless, the rules governing the economic effects of divorce differ significantly in particular EU Member States. Because of this, the international couples face the practical and legal difficulties in case of property division upon divorce (European Commission, Proposal for a regulation [online], 2016, p. 4). *“The great variety of solutions adopted by each Member State creates a situation of uncertainty for spouses who may find themselves subject to different matrimonial property regimes, which depend on the court having jurisdiction. Moreover, this may lead to disadvantageous consequences for the rights of third parties, as well as the effective exercise of the right of free movement of persons”* (Viarengo, 2011, p. 200). It might therefore be difficult for the international couples to foresee, which rules will apply to their property relations, and what the economic consequences of the divorce will be.

After many years of preparations, negotiations and searching for political consensus, the Council regulation 2016/1103 implementing enhanced cooperation in the area of jurisdiction, applicable law and the recognition and enforcement of decisions in matters of matrimonial property regimes (“Regulation”) was enacted in June 2016. The Regulation seeks to eliminate the obstacles to the free movement of persons, especially the difficulties experienced by the international couples in dividing their property upon divorce (Recital 8 of the Preamble to the Regulation).

It follows that the current social and legal reality regarding the distribution of matrimonial property of the international couples upon divorce represents a great challenge for the ongoing European integration. The aim of this paper is to analyse whether the newly adopted EU instrument provides for the effective and predictable solution of the economic effects of divorce. With regard to the limited extent of this contribution, the author will only examine the background and adoption of the Regulation from the point of view of the determination of the law applicable to matrimonial property regimes. It will not deal with the matters of jurisdiction, and recognition and enforcement of judgments, which are beyond the scope of this paper. In the concluding part of this article the author will summarize her findings and provide a brief assessment. In order to achieve the purpose of this paper, the author will in particular use the descriptive method, and the methods of analysis and synthesis.

## **2. General Background and Possible Solutions**

Even the internal market might be considered an area without the factual internal frontiers, the legal barriers persist in particular matters (Týč, 2017, p. 242). This is also true in matters of

matrimonial property regimes, because substantive law differs substantially among the EU Member States. While most continental legal systems make use of the regimes of community of property, the common law countries prefer a separation of property (Scoles, 1989, pp. 17–18). Each state therefore subjects the spouses to a specific set of rules, which governs their financial relations (Scherpe, 2012, p. 1). Besides, divergence exists with regard to the conflict-of-law rules; some states determine the law applicable to matrimonial property regimes of the international couples according to the connecting factor of nationality of the spouses, others use domicile of the spouses. Lately, the concept of habitual residence has become utilized as well (Scoles, 1989, pp. 23–24; see also Kroll, 2008, pp. 380–383).

The abovementioned disparities are caused by the fact that family law including matrimonial property law is based on different national, historical, legal, and cultural traditions and background in each particular state (Dvořák and Spáčil, 2011, p. 6). Over the last few decades the EU has adopted several legislative instruments in order to help the EU citizens with the cross-border disputes (Marcos, 2013, pp. 96–109); including the regulation on the law applicable to divorce and legal separation (“Rome III regulation”) (Viarengo, 2014, pp. 547–559). Nevertheless, none of them is applicable to the economic effects of divorce (Viarengo, 2011, p. 200). Those remain subject to national law (Kroll, 2008, p. 380).

In order to demonstrate persisting problems, we can give an example. The spouses, the Czech nationals, have been living and working in Austria for several years. Besides, they own immovable property (for example house) in Germany. The spouses decided to file a divorce petition in a court of an EU Member State, which we presume to have jurisdiction in this particular case. The spouses also want this court to distribute their matrimonial property upon divorce. Hypothetically (depending on the used connecting factor), the rules of three EU Member States may be applicable. Provided other requirements are fulfilled, it can be the Czech, Austrian or German law. Accordingly, three different matrimonial property regimes might be at stake. In compliance with the Czech substantive law, the limited community of property (community of acquests) will be divided upon divorce. In conformity with Austrian law, a separation of property will be utilized. If German law is applicable, the regime of community of accrued gains will be liquidated. In any case, the extent of the property to be granted to each spouse (i. e. spouse’s share in property) upon divorce will more or less vary according to the applicable legal system (see also Pintens, 2011, pp. 20–36, 41–44).

There is no doubt that the absence of uniformity in the area of family law “*creates as obstacle to the free movement of persons and the creation of a truly European identity and an integrated European space*” (Boele-Woelki, 2005, p. 161). Because, the existing differences may prevent the international spouses from moving among the EU Member States, if they worry it might affect their matrimonial property rights (similarly Baarsma, 2011, pp. 3, 96). Theoretically, the outlined problems can be resolved in two ways. Firstly, harmonization or unification of the substantive law rules governing the economic consequences of marriage and divorce is possible. According to the second approach, the unified conflict-of-law rules (i. e. common rules determining the applicable law) in matters of matrimonial property regimes can be adopted at EU level (similarly Van Erp, 2010, p. 6). Even though, the unification of the substantive law rules would be more effective, the unification of the conflict-of-law rules is more realistic in the current state of development. Moreover, the conflict-of-law method provides for respect for the existing diversity in the national legal systems (Rozehnalová, 2013, p. 19).

Additionally, we have to consider whether the EU has competence to legislate in this sphere of law. Because there is no provision transferring competence to the EU in matters of domestic family law, it is clear that substantive matrimonial property law falls within the exclusive

competence of particular EU Member States (Art. 3 of the TFEU *a contrario*). Nevertheless, shared competence between the EU and the Member States exists as regards the area of freedom, security and justice, which also covers the judicial cooperation in civil (including family) matters having cross-border implications (Art. 4 para. 2(j), Art. 67 para. 4, Art. 81 of the TFEU; Fiorini, 2012, pp. 5, 8).

Without going into many details, we can summarize that the only possibility the EU legislator had was to adopt regulation and unify the conflict-of-law rules in matters of matrimonial property regimes. The conflict-of-law rules do not provide for substantive regulation; they only determine the national law of which state is best placed to govern the legal relationship in question.

### 3. Adoption of Regulation and Enhanced Cooperation

As a rule, the process of adoption of measures concerning family law having the cross-border implications is much slower than in other civil and commercial matters (Fiorini, 2012, pp. 6, 12). The reason is that they have to be enacted in accordance with a special legislative procedure, i.e. unanimously by the Council of the European Union after consulting European Parliament (Art. 81 para. 3 of the TFEU). But, the sensitivity of family law matters makes it uneasy to obtain consensus (Kuipers, 2012, p. 213). Similarly, the EU Member States failed to reach unanimity necessary for the adoption of the proposal for the regulation in matters of matrimonial property regimes, because Poland and Hungary raised their objections. Afterwards, the Council concluded that “*the objectives of cooperation in this area could not be attained within a reasonable period by the Union as a whole*” (Recital 10 of the Preamble to the Regulation).

Nevertheless, 18 EU Member States declared their intention to establish so called enhanced cooperation between themselves in matters of matrimonial property regimes of the international couples (Recital 11 of the Preamble to the Regulation; more to enhanced cooperation see Art. 20 of the TEU; Arts. 326–334 of the TFEU). Enhanced cooperation is a mechanism that allows establishing advanced cooperation of a group of EU Member States. These states are permitted to move at different speeds and towards different goals than those Member States, which decide to stay outside enhanced cooperation. Enhanced cooperation can only be undertaken as a last resort, where the EU as a whole is unable to achieve purpose of this cooperation within a reasonable time. At least nine Member States must participate in it. In addition, other prescribed conditions have to be fulfilled (Týč, 2017, p. 58).

On 9 June 2016, the Council enacted decision authorising enhanced cooperation in matters of matrimonial property regimes. The Regulation itself implementing enhanced cooperation in matters of matrimonial property regimes was adopted on 24 June 2016 (Recital 12 of the Preamble, Art. 70 of the Regulation). This implies that the Regulation will be binding and directly applicable only in the EU Member States, which participate in enhanced cooperation (so called “participating Member States”). Those are Austria, Belgium, Bulgaria, Croatia, Cyprus, the Czech Republic, Finland, France, Germany, Greece, Italy, Luxembourg, Malta, the Netherlands, Portugal, Slovenia, Spain, and Sweden (Recital 11 of the Preamble, Art. 70 of the Regulation). In this respect, we can appreciate that the Czech Republic decided to get involved in enhanced cooperation too.

It should however be noted that enhanced cooperation on the Regulation is at any time open to all EU Member States, provided they comply with the prescribed requirements. Of course, participation of as many EU Member States as possible is desirable (Art. 328 para. 1 of the TFEU; Recital 13 of the Preamble to the Regulation). Accordingly, Estonia announced its

intention to take part in this form of cooperation as well (Council of the EU [online], 2016). We can consider this as first success. Hopefully other will follow.

In this respect, we must critically assess whether enhanced cooperation in matters of matrimonial property regimes will contribute to further the objectives of the EU and its integration process (similarly Boele-Woelki, 2009, p. 11). Boele-Woelki talks about a “two-speed European Union” and states that “*the cooperation of all Member States ends where the enhanced cooperation of some Member States begins*” (Boele-Woelki, 2009, pp. 4, 13). Pauknerová declares enhanced cooperation as one of the limits of the unification of European private international law (Pauknerová, 2017, p. 186). It is obvious that enhanced cooperation cannot achieve the purposes of European family law in the same way as an EU regulation adopted by all Member States (Fiorini, 2012, p. 15).

Nevertheless, the answer is not so straightforward. Enhanced cooperation can have both positive and negative implications. On the one hand, enhanced cooperation may be seen as a tool, which frustrates the cooperation of the EU as a whole. On the other hand, unanimity on a family law measure cannot be reached at all costs. Moreover, successful enhanced cooperation might inspire the non-participating Member States to join enhanced cooperation at later stage (Boele-Woelki, 2009, p. 13; for thorough analysis of enhanced cooperation in the context of Rome III regulation see Peers, 2010, pp. 339–358; Kuipers, 2012, pp. 201–229). What is more, the total population of eighteen participating Member States was approximately 356.5 million in 2017, which represented almost 70 % of the EU population (Eurostat, Population [online], 2018). We can therefore presume that a significant number of international couples will benefit from enhanced cooperation on Regulation in practice.

To sum up, the Regulation was “*designed to fill in a very serious gap in the process of the European unification of private international law rules in the field of family law*” (Bonomi, 2014, p. 231). The Regulation should facilitate the proper functioning of the internal market by eliminating the obstacles to the free movement of persons who currently face problems due to differences between the national law rules concerning the economic consequences of international marriage (European Commission, Proposal for a decision [online], 2016, p. 10). In order to guarantee legal certainty and predictability of solution for the international couples, the Regulation introduces the unified conflict-of-law rules, which will be identical in all participating Member States, in which they will replace the different national conflict-of-law rules (European Commission, Proposal for a regulation [online], 2016, pp. 5–6).

#### 4. Conclusion

The free movement of persons constitutes one of the principal elements of the European single market, not only for the economically active persons, but also for all EU citizens. It is indisputable fact that the increased integration and greater mobility of persons within the EU result in an increase in the cross-border legal relationships, including family law relations such as international marriage and divorce. From an economic point of view, the property effects of the dissolution of international marriage by divorce are of utmost importance.

Nevertheless, the existing situation, in which both substantive law and the conflict-of-law rules regarding the economic consequences of divorce vary greatly among the EU Member States, does not offer sufficient legal certainty to the couples who decide to make use of their right to free movement, because the courts of the EU Member States apply different rules in particular cases. This may consequently lead to diverse results; for example each spouse’s share in common property upon divorce may vary considerably depending on the court having jurisdiction. The ongoing European integration has thus created a new challenge for European

legislator – the need for the unification or harmonization of family law including matrimonial property law.

Since the EU has no competence to harmonize the rules of substantive family law, the EU legislator focused on the unification of the conflict-of-law rules in matters of matrimonial property regimes. The Regulation, which was successfully enacted in June 2016, will be applicable as from 29 January 2019 (Art. 70 of the Regulation). One of the purposes of the Regulation is to establish common legal framework for the determination of the law applicable to the matrimonial property regimes. The Regulation aims to eliminate the obstacles that the international couples face, both in everyday management of their matrimonial property and in case of its distribution upon divorce. The unified conflict-of-law rules should contribute to greater legal certainty and predictability of solution in each particular case, irrespective of the competent court seized.

The fact that the Regulation was only adopted by way of enhanced cooperation (i. e. not all EU Member States are bound by this instrument) seems to be the most problematic. It should be emphasised that it is very difficult, or even impossible, to overlook the consequences of enhanced cooperation at this stage of development, because the Regulation is still not applicable. After a certain period elapsed, a comparison and evaluation will certainly take place, as well as a review procedure that is foreseen by the Regulation itself (Art. 68 of the Regulation). Enhanced cooperation does not probably constitute the most preferable solution, especially in family law matters. However, author considers this at least a step in the right direction, which could simplify the situation of the international couples in what are often the difficult moments of their lives. We can hope that the non-participating Member States will reconsider their present attitude and decide to join enhanced cooperation later.

### ***Abstract***

*Whole paper is about new Financial Directives of the European Union and their impact on the financial market. The individual directives are called UCITS (Undertakings for the Collective Investment of Transferable Securities) and follow UCITS I. to V., which is in force from 2014 with use to individual member states' legislation in 2016. Alongside, directive MIFID II and MIFIR – Financial Instrument Regulation, entered into force on 01/01/2018. The main objective is to ensure investors' protection across the European Union. The article deals with the real impact of these directives on financial markets in the European Union, especially in the Czech Republic. It seeks answers to questions on how individual member states and in particular financial actors adapt to the application of these current directives.*

***Keywords:*** Financial Directive, Financial Market, MIFID, UCITS

***JEL Classification:*** G18, G21, G19

### **1. Introduction**

Although financial markets are based on a market principle, this principle is not the only determinant of real events in the context of these markets. Due to the particular disposition of the financial markets, it is desirable and necessary to provide adequate regulation, which would be directed to increase the transparency of trading on the markets and ensure that market participants are aware of all relevant aspects relating to the subject of trade and other related consequences.

The important factor in this view is the legislation that often influences the financial markets in a crucial way with a set of concrete measures. The aim of this paper is to introduce institutions dealing with financial market regulation and to evaluate the impact of these institutions and directives on financial markets throughout the European Union. Descriptive and analytical methods are used to fulfill the stated aim.

The following chapters are focused to the introduction of the Investment Company Association, European Fund, Asset Management Association and the MiFID II directives. The defined institutions and directives on the financial markets throughout the European Union are also being analyzed.

### **2. Financial Directives in the EU**

Since 2007, there have been major changes in the regulations governing the financial markets. The following chapters will provide how the changes impact the EU financial market.

## 2.1 Investment Associations

**ICA** (Investment Company Association) is the American Association of Investment Companies. There is an analogy with the British AIC (The Association of Investment Companies), which behaves as an association for investment companies. Association ICA represents wide range of investment companies in the form of investment funds, subsidiary investment companies and other relevant subjects.

The effect of ICA in financial markets is relatively high, which illustrates the case about frequency of disclosure. In this case, Investment Company Association decided with a more frequent disclosure of the portfolio, the overall return on shared funds' shareholders would probably be lower than under the current disclosure standard. Thereby, the standard would be maintained (Hughen and Laatsch, 2018).

Frequent data publishing would increase transaction costs and frequent disclosure of portfolio information would facilitate free management of fund selection, which could unfavorably affect returns if idle activity occurs before institutions are able to set the required position in the price.

Importance and influence of the Investment Company Association on the financial markets determines the United States' position as the largest headquarters for investment funds, which for the year 2013 has shown 45% of the total market share. Europe with 37% has placed on 2nd place, while 7% of the world's investment fund has been created by emerging countries. Countries like Japan, Canada and Australia account have created 12% of the market (EFAMA [online], 2018a).

**EFAMA** (European Fund and Asset Management Association) is a European Investment Management Association. EFAMA represents 28 member associations and 62 corporate members, with almost 23 trillion € of managed assets, of which 14,1 trillion € is allocated to 58,400 funds (the end of 2016). More than 30,600 of these funds fall under the UCITS and the remaining 27,800 funds are under Alternative Investment Funds (EFAMA [online], 2018b).

The organization was founded in 1974 under the title "European Federation of Investment Funds and Companies" (using the French acronym FEFISI). Founding countries were Belgium, France, Germany, the Netherlands, Ireland, Italy and United Kingdom. The organization is planning on a rotation basis, where no permanent headquarters' place is established, only a permanent secretariat is permanently based in Brussels. The fundamental change in the organization's existence came in 2004, when the constitution's articles changed to represent the investment fund and asset management.

The impact of EFAMA on the financial markets is significant. The impact currently affects EFAMA's positive forecasting of asset fund developments. The overall growth in UCITS and non - UCITS assets correlates significantly with the development of future economic growth and exchange rates. This is the case, where the net sale of funds is heavily influenced by the economic prospect and the level of exposure of investment funds to shares. Due to close links between investment fund assets, real GDP and exchange prices, EFAMA predicts an asset growth of between 15.1 - 21.3 trillion € by 2020 (with a modulation of the scenarios of pessimistic, standard and optimistic scenarios) (EFAMA [online], 2018a).

The essential factor influencing EFAMA and its influence in the current conditions is unknown impact on Brexit. Financial harmonization is necessarily given in this connection in the context of globalization (Greenwood and Roderer-Ryning, 2015, p. 325-338). Even though the United Kingdom withdrawal from the European Union has not been debated yet, it is already showing up in the negotiations. Britain, as a key component of EFAMA, can potentially weaken the

influence of the institution. From 62 EFAMA's corporate members, 25 branches are based in London (IPE [online], 2018).

Another significant impact of EFAMA on the financial market takes place in connection with the PRIIPs - Regulation of the European Parliament and of the Council (EU) nr. 1286/2014 by the 26 November 2014 on key product information documents. With effect from January 1<sup>st</sup> 2018, this new European regulation sets out the obligation for banks to provide retail clients according to MiFID categories a Key Information Document (KID) for retail and investment products to improve transparency and facilitate comparison of information relevant to investment activities (Groupe Societe Generale [online], 2018).

EFAMA opposes these PRIIP rules, arguing that they can cause serious damage to investors by providing the required data (particularly in terms of performance and cost). In the best case, it may only confuse investors and, in the worst case, mislead them. Because of this, there is a risk of disturbing confidence in the investment products and in the provided information to investors. EFAMA insists that investors are provided with truly reliable and non-verifiable information about the products on which the resulting decision about investment is based (EFAMA [online], 2018c).

## ***2.2 Financial Directives and their Impact in the EU UCITS***

The highest level of collective investment regulation is in the area of European law in the form of EU regulations and directives. This is primarily a UCITS and AIFMD directive. UCITS is a pan-European regulatory framework that allows to manage and sell investment instruments across the Europe. The fund is structured to allow retail investors access to sophisticated, active strategies that are comply with liquidity and transparency restrictions secured by regulatory oversight. The already analyzed shift in the mindset of an investor seeking returns on hedge funds has led to a substantial increase in UCITS funds. For March 2017, the LuxHedge database reported 420 billion € in assets under the management of 1,380 funds operating under sixteen different strategies (Bouamara etc [online], 2017).

UCITS forms the collective investment standards enshrined by the European Union in the context of the collective investment of transferable securities. It defines the rules and legislation on investing in collective investment securities. The abbreviation UCITS means "Undertakings of Collective Investments in Transferable Securities Directive" (Szylar, 2013). The regulations are transposed into the Collective Investment Act (not applicable to trading in capital market).

The history of UCITS dates back to 1985, when UCITS I was published to create a single regulatory framework for mutual funds in the context of Europe (the so-called "European passport" for funds). Luxembourg was the first in 1988 to implement the UCITS, and seven UCITS' funds were established during the coming month. In 1999, over 3 trillion € was invested in UCITS' funds (Muller and Ruttiens, 2013). UCITS therefore constituted a certain authorization by which the investment companies of the member states could sell their products also in the territory of other states of the European Community. A major amendment took place in 2001 in the form of Directives 2001/107/EC and 2001/108/ES, i.e. UCITS II and UCITS III. The main objective was to strengthen investors' confidence in collective investment on a global scale (Moloney, 2002).

Therefore, investor's protection was strengthened by abolishing restrictions and diverging approaches across countries (Beaudoin and Olivier, 2010, p. 20-24). Also, appropriate conditions have been put in place to prevent conflicts between investors and fund managers, so investment management does not prioritize its interests over the interests of prime investors.

For greater transparency, the obligation to standardize the calculation of total costs was established “TER” (Total Expensive Ratio) and this result published within the fund (UCITS XXV [online], 2018).

In 2009, the directive called UCITS IV, which was once again implemented first by Luxembourg (this time with five other countries), was approved. At the end of 2010, nearly 6 trillion € was invested in more than 36,000 UCITS funds. UCITS IV covers and modifies all previous UCITS directives with extension to standard fund mergers, disclosure for investors, disclosure of risk ration and return (SRRI - Synthetic risk and reward indicator). UCITS V amended the UCITS IV directive in 2014, in the framework of the activities of depositaries, remuneration and sanction principles with effect from 18<sup>th</sup> March 2016.

UCITS can be grasped as a trend of European Union regulation to shift attention from increasing regulation in the area of consumer protection to regulating market protection as such as increasing its transparency (Anderberg and Bolton, 2006, p. 13-18). One of the main UCITS’ motives is the investor’s protection as a consumer of the financial market. UCITS is aimed at protecting the customer’s assets, setting appropriate limits, diversification and asset classes into which the fund manager can invest.

UCITS is used to set basic standards to protect investors. Similar forms of standards have been introduced in other areas of the capital market, f.e. in relation to the provision of investment services through Directive 2004/39/EC of the European Parliament and of the council on markets in financial instruments (MiFID). The protection of the market itself should also provide consumer protection through mediation.

It is important to clearly define the role of the entity within the financial market for the application of UCITS. In this aspect, it is being used the exhaustive identification of the activities, which are the usual attachment of the individual adjustments. E.g. very precise is the identification of areas of activity that includes administration - activities that are related to the investment fund but which can no longer be included under the definition of management.

Administrator is the entity that deals with clients, but clients do not directly allocate their assets into his management - the administrator acts as an intermediary. Currently, there is a valid exhaustive list of UCITS activities. This is analogous to the AIFMD enumeration, consists of f.e. bookkeeping activity, legal services, compliance and internal audit, investor complaints solving, valuation of assets and debts, valuation of the book-entry securities issued by the fund etc.

The significance of UCITS is particularly important in the field of the harmonization laws and regulations concerning collective investment in the member states of the European Union. Due to regulatory steps, UCITS funds can be compared to each other according to the obligation to publish exhaustively defined data and the methodology of calculations. Together with MiFID, this adjustment increases transparency in the financial markets.

In the UCITS scheme, the public policy applies. This public policy excludes the possibility of creating private funds addressed only to a narrow circle of investors. The public’s principle is linked to the transparency and disclosure of facts that have important information value for investors, in particular under the rules for the creation and publication of founding documents, statutes, prospectuses and annual reports.

UCITS also provide provides diversification of risk in the promotion of collective investment activities. The limits are derived from two criteria: the amount of the assets of the collective investment undertaking (assets in a single entity’s portfolio may not consist of more than 5% of the money or capital market instruments issued by one issuer - but there are exceptions, e.g.

for an index fund with a limit of 35%) and the volume of the issue of the acquired title (the volume of the shares must not have a significant effect on the issuer's management - 5%, for other securities this limit is 10% of the volume of paper from one issuer and the securities issued by other collective investment undertakings 25%). Commission Directive 2007/14/EC laying down detailed rules for the implementation of certain provisions of directive 2004/109/EC on the harmonization of transparency requirements in relation to information about issuers whose securities are dealt in on a regulated market.

Limits are stated deliberately, with the need to indicate a potential negative, which is based on a high degree of restraint, where the directives specify precisely what investment limits and investment instruments UCITS can invest in. There is a question of how to determine the right boundary between the potential release of investment limits and investor protection, or the extent to which funds are harmonized.

### **MIFID**

The regulation in the form of AIFMD (European directive determining the legislation on investing in alternative fund securities - Alternative Investment Fund Managers Directive) is based on different objectives than UCITS. The origins of the AIFMD are related to the implementation period in which Europe was in a deep economic crisis. The adjustment is intended to mitigate or prevent some of the negative effects that have allowed the crisis to develop into a global dimension (Beythán and Virard-Canto, 2012, p. 64-72).

However, a common element with UCITS lies in the focus on market protection with a secondary impact on consumer protection (European Commission [online], 2018). A new fund adjustment under AIFMD focuses on large entities that manage assets over 100,000,000 € or 500,000,000 € if such company does not leverage or the fund is closed for at least five years.

In domestic conditions, the AIFMD directive has been transposed to take an advantage of the opportunities offered by the directive. Special funds designated for the public (alternative to the UCITS) are thus automatically subject to AIFMD adjustment regardless of the volume of assets in the fund assets. According to that is the special fund manager entitled to exceed the applicable limit. However, the risk distribution remains more stringent than in the AIFMD requirements. Special funds also include a European passport with the possibility to offer them in other EU countries (MFČR [online], 2018).

The new regulation of AIFMD mainly applies to high volume investment funds, precisely hedge funds. If there is bad hedge fund management, the adverse effects are also transferred to the management of the hedge fund, which affects the entire economic system. This trend towards market transparency and integrity is also reflected in the directive of the European Parliament and the Council 201/65/EU on markets in Financial Instruments (MiFID II), which strengthens the transparency of market infrastructure within derivatives markets (directive 2014/65/EU).

The MiFID Directive fundamentally determines the activities realized in the markets of financial instruments (Tanzi et al., 2013, p. 51-68). In some cases, MiFID also speaks of a revolution (Wojcik et al., 2007, p. 167-173) and occasionally in connection with lobbying (Woll, 2013, p. 555-572). MiFID II is seen as clearly stricter rules for regulating European financial markets (Busch, 2018, p. 126-142) (Busch, 2016, p. 72-82).

Currently, MiFID II prohibits asset managers from using research that they have not paid. It is the European Union's interest in suppressing investment research. It will be illegal for asset managers to obtain research for which they have not paid, creating unprecedented information

asymmetries among managers based on their ability/willingness and available research budget (IPE [online], 2018b).

The origin of this change can be traced back to the UK Myners report of 2001, which was set against the linking of research commission costs. Currently, asset managers offer solutions to absorb research costs by creating a research payment account (RPA) for customers. Two models are used here (IPE [online], 2018b):

- *Accounting (Swedish) model* - originally designed in the early versions of the MiFID II guidelines, with promotion especially from Scandinavian fund managers. According to the model, the asset manager sets a separate annual research fee which will be charged directly to the client to absorb all the costs of research that the manager uses on behalf of the client. To cover payments, monthly or quarterly payments are used, depending on a reasonable amount of time to the frequency with the entity makes payments to its research providers.
- *Transaction Approach* - An asset manager performs research on business mediation to absorb transaction costs.

Both approaches implement the fact that research budgets cannot be determined by the volume or value of transactions, and they need to be aggregated at the client level. If the cost of research exceeds the budgets, administrators have to reimburse these costs from their own resources. In addition, administrators are required to disclose which investment research providers do they use, why and how research benefits their clients.

If the main importance and purpose of the instrument is to be identified in the financial market, then it is undoubtedly the interest in ensuring transparency of clients' awareness of individual products (see MiFID II) and the implementation of clear rules (see EFAMA). As a part of the client's protection, a trend based on relationship between the protection of the market itself and the client is also applied. With this trend, positive effects will also move to the client protection.

### 3. Conclusion

The impact of this regulation in the form of directives and institutions has a major impact on the whole EU market with the commitment for EU members to these directives. However, apart from the impact of the directives themselves, every proverbial party proclamation on the market also affects the behavior of participants in the relevant markets.

From the actual and specific measures was mentioned the influence of the Investment Company Association on the frequency of portfolios in the context of mutual funds with the argumentation of the impact on revenues. EFAMA has issued a positive prediction on the development of fund assets in relation to all development scenarios. EFAMA also has an impact in relation to PRIIPs in its obligation (in effect from 1 January 2018) to provide banks with a key information document for retail clients in order to increase trading transparency. EFAMA has defined against this rule when it could be confusing for investors. A separate question within EFAMA is further development after Brexit.

The UCITS (which establishes the collective investment standards embed in the European Union) determines the rules and legislation of collective investment. The adjustment is aimed at strengthening investors' confidence with their protection and the unification of national conditions. Individual measures have a long-term effect on reconciling the interests of stakeholders with market regulation. UCITS provide diversification of risk, transparency and

trading limits. MiFID II currently operates in the line with the European Union's interest in suppressing investment research. Accounting (Swedish) model and transaction approach is offered as a solution.

On the basis of the above the stated objective has been fulfilled. The paper provides a presentation of institutions dealing with financial market regulation with an assessment of the impact of these institutions (and financial directives) on the financial markets in the context of the European Union.

### **Abstract**

*In the article, the theses are proved – Ukraine's ambitions for European integration should be supported by the necessary measures, namely: an open competitive economy formation; a single market development and society with high-quality goods (above all, food products) providing; socially responsible marketing and ecomarketing introduction. The purpose of the article was the role and priorities of marketing standards development in the context of European integration processes challenges to substantiate. To achieve this goal, appropriate methods were used: comparative analysis and content analysis of scientific and popular sources as well as its logical analysis, induction and deduction. The study was conducted in 2016–2018. Based on the analysis, the following priorities for the development of marketing standards have been identified: macro-marketing standards in the “state – business” system, eco-marketing standards in the three-level “state – business – consumer” system, micro-marketing standards in “consumer-oriented enterprise” system.*

**Keywords:** *eco-marketing standards, EU integration processes, macro-marketing standards, micro-marketing standards*

**JEL Classification:** *F20, F60, I10, M30*

## **1. Introduction**

In the context of the transformation of economic relations, the globalization of world markets, the instability of the market environment, a new phase of Ukraine's integration into the world economic space and the construction of new political and economic systems, there is a need to improve existing and find new ways to ensure economic development.

This need, in the face of growing competition, is facing not only Ukraine but, for our country, it has become a complex problem. An indication of the relevance of this problem is the Global

Competitiveness Rating of the World Economic Forum (WEF), according to which Ukraine occupied in 2017-2018 the 81st position out of 137 countries (Ekonomichna pravda [online], 2016). This indicator turns into an eloquent proof of the complexity of existing systemic obstacles in achieving the goal, if we recall its dynamics in 2011-2017, particularly: 89, 73, 84, 76, 79, 85, 81 (Kupe and Mackonina [online], 2016). And the graphic representation of this dynamics is a sinusoid that holds firmly between the 73<sup>rd</sup> place (2012) and the 89<sup>th</sup> place (2011) and does not show a trend towards improvement.

## **2. Problem Formulation and Methodology**

A serious problem is the creation of such economic conditions that would finally make it possible to ensure the presence of three basic determinants, namely: 1) science, technologies and innovations development; 2) investment in industry and agriculture increasing; business models improvement; and all this will contribute to the proper quality and corresponding technological level of industrial products production growth.

It is clear that the above conditions/factors will not gain the necessary weight without the proper openness of the markets which in turn updates and strengthens the importance of the standardization system in solving the problems of economic growth.

### ***2.1 The Purpose of the Article***

The purpose of the article was the role and priorities of marketing standards development in the context of European integration processes challenges to substantiate.

### ***2.2 The Methodology of the Study***

To achieve this goal, appropriate methods were used: comparative analysis and content analysis of scientific and popular sources as well as its logical analysis, induction and deduction. The study was conducted in 2016–2018. Based on the analysis, the following priorities for the development of marketing standards have been identified: macro-marketing standards in the “state – business” system, eco-marketing standards in the three-level “state – business – consumer” system, micro-marketing standards in “consumer-oriented enterprise” system.

## **3. Problem Solution**

According to Directive 98/34 / EC, European standards are certain technical specifications adopted by the European Standardization Organizations for the purpose of their use several times, often or even permanently. However, their compliance is not obligatory (Organ Certyfikacji [online], 2017).

Countries that have an objective to cooperate with the EU must adhere to these standards by establishing national standards as closely as possible (harmonized) with EU standards. Recently, in the publications, we find the definition of harmonized standards as a special category in the European standards. However, in fact, "harmonized standards" – a relatively new special term, which is used in the Directives of the New Approach to Standardization, with a view to the legal determination of technical specifications, more commonly known as "European Standards". It follows from this that the special role of the Harmonized Standards

is often exaggerated because, in the Directives of the New Approach to Standardization, harmonized standards are of a purely advisory nature (Dzieńdziora, Smolarek, 2016).

According to the New Approach directives, harmonized standards will only come into force when standardization organizations of European products formally transmit such standards to the EU Commission for consideration and determine the same requirements to products. Next, the EU Commission together with the European Standardization Organization at the official level issue a mandate.

Continuing the process, organizations responsible for the standardization of European goods receive an official position in accordance with a mandate developed by domestic law. The period of non-interference begins when a mandate is adopted and a working program of the activities of these organizations is developed. The very period of non-interference is aimed at regulating the standards, that is, no state body at the national level has the right to develop a national standard if such (identical) standard already exists in the category of European standards (Kovalchuk, 2016).

It should be noted that the development of standards in the European Union is primarily aimed at achieving the following three global goals: the formation of an open and competitive economy; the development of a single market and the provision of quality food products to society; the creation and use of effective business models, as well as their coordination with the processes of standardization of products and enterprises in general. Taking into account the above, it is expedient to consider in detail the mentioned goals in the context of their comparison with the integration tasks of Ukraine.

### ***3.1 An Open and Competitive Economy Formation***

The European Commission defines competitiveness as "... the steady growth of living standards of a nation or region and the lowest possible level of forced unemployment" (Potapenko, 2012, pp. 23-38). Since there are sufficient definitions of competitiveness, we restrict ourselves to their brief generalization – competitiveness (at least in the long run) can be determined by the level of productivity of the enterprise, the nation, the region and ensure the following (Manuilovich, 2013; Ocinka perspektiv, 2017; Schroder, 2011):

- "reasonable" growth, that is, the growth of an economy based on knowledge and innovation;
- steady growth, namely, promotion of the more efficient use of resources, development of an environmentally-oriented competitive economy;
- multi-vector growth by stimulating an economy with a high employment rate, which will promote social and territorial cohesion.

Such a comprehensive growth is impossible without due attention to the personnel potential, which still remains high enough in Ukraine, despite the prolonged and powerful "brain drain". In our opinion, the priority and urgent task should be to preserve, encourage and fully support human resources with an emphasis on engineering and scientific personnel. And only in such a way will it be possible to realize the following (derivative) tasks, which we include: a) the development of information and communication technologies (in terms of improving the quality and accessibility of communications, increasing the level of coverage of the Internet in educational institutions, etc.); b) to increase the size of the market of innovations by reloading scientific institutions and transforming them into creative, capable institutions open to cooperation with business and the international community in accordance with the principle of "science without borders" (Esmailpour and Hoseini, 2017).

Therefore, today it is necessary to form the basis for the achievement of the specified tasks. In particular, during the development of standards, it is very important to take into account innovative processes and trends, achievements in science and technology, thus bringing the state of the Ukrainian market in line with the requirements of international and European standards. It is clear that under such conditions, the sale of products on the international or European markets will emerge from the threats that currently exist due to technical barriers to trade (Simarmata and Keke, 2017).

### ***3.2 A Single Market and the Provision of Quality Food Products to Society Development***

The European internal market originates from 1951, and its final formation took place in 1985 with the adoption of the White Paper "Completing the formation of the internal market" (Reshota [online], 2012; Okreglicka, Gorzen-Mitka and Ogreaan, 2015; Barcik, 2016; Mynarzová, Kaňa and Okreglicka, 2016). In this book, it was proposed to eliminate the physical, technical and tax borders for the free movement of goods, persons, services and capital between EU member states. This, in turn, led to the creation of new strategies for economic development, stimulated the search for new concepts and actions, methods of sales and contacts with the market (Dziwiński, 2016). The combination of these and many other innovations gradually began to be called Euromarketing in the EU countries (Germany, France, Spain, Poland, etc.).

According to Y. Wiktor, "Euromarketing is a list of principles of the company's activity on such a specific international market as the EU internal market" (Gołab-Andzejak, 2015). Such a market simultaneously combines two opposite characteristics. On the one hand, it is homogeneous, since it is formed under the influence of the market mechanisms regulating the single EU member states: there are common rules for doing business, antitrust laws, a common trade policy; is based on the principles of economic freedom, without the use of protective customs barriers, free movement of capital, population, material goods, etc. However, on the other hand, it is heterogeneous, since each country has different levels of social and economic development, cultural characteristics, religion, historical values and assets, and so on. And such in this context, an extremely important element of the development of standards in the EU is the focus on a "stronger, deeper and wider single market".

The given brief historical certificate testifies to the importance of the in-depth study of the whole spectrum of factors, which ultimately determine the very possibility of integrating Ukrainian enterprises into EU markets and the prospects for ensuring their competitiveness. In any case, two tasks are indisputable.

The first. Ukrainian entrepreneurs should maximally focus on compliance with EU standards (at all stages of development, storage and transportation of products), as well as the positioning of their products in accordance with the ratio in the "price-quality" system adopted on European markets. These two benchmarks are a prerequisite for the successful development of any enterprise and the release of its products on new markets. In this context, it is important to pay attention to the choice of reliable suppliers of quality raw materials, the proper level of input control, and so on. Given that a significant part of Ukrainian standards has not been updated for a long time, the Ukrainian companies faced an urgent requirement: to participate in monitoring the process of updating EU standards (which are directly dependent on market requirements) and try to be relevant to them. In a rapidly changing market situation, the need to update these standards becomes without exaggeration a vital task.

The second. It is necessary to create a multifunctional system of integrated communications, intended to provide information producers (on potential sales markets) and consumers (on the diverse products of producers). The above suggestion follows from the results of the World Bank research, according to which about half of the exporting enterprises, among the restrictive factors of commercial character, note the lack of means for examining export markets, as well as insufficient consumer awareness, which reduces the pace of promotion of their goods and services (Svitoviy Bank [online], 2018). The level of informing potential consumers about goods or services should be appropriate.

### ***3.3 Effective Business Models Creation and Using***

Globalization processes in the economy and strengthening of non-price competition stimulate enterprises to find innovative ways of development which are connected primarily with the problems of improving the quality of manufactured products, adapting it to international requirements (Harris, Sithole and Kibirige, 2017). However, for the vast majority of Ukrainian small and medium-sized enterprises, these problems are combined with the problems of harmonizing standards for the production of own products with European standards. After all, processes of harmonization and adaptation of legislation in the field of technical regulation require not only a long time but also significant material resources, which in a large number of enterprises simply do not exist. For information: the total cost of adapting to the EU standards of only one sector – the meat industry – Poland amounted to about 2 billion euros (Ocinka perspektiv, 2017).

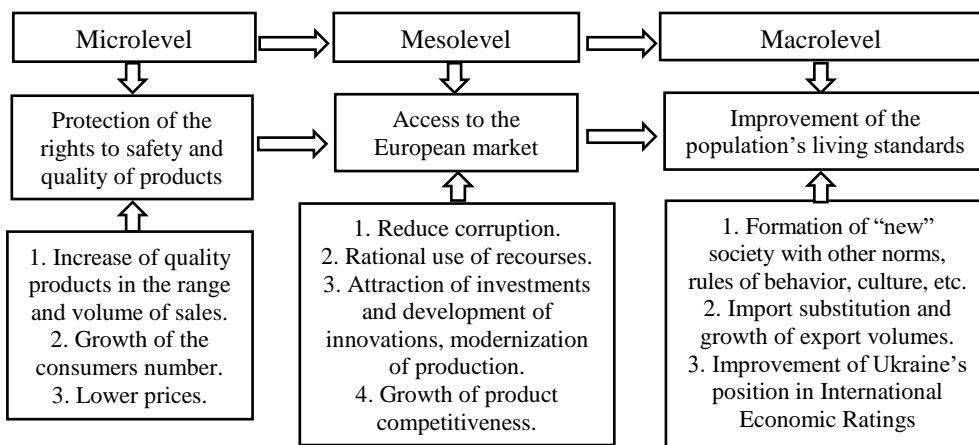

At the same time, in accordance with Article 17 of the Association Agreement between Ukraine and the EU, cooperation between the parties will also cover the promotion of policies in the areas of product standards, production requirements and quality schemes (Slyva [online], 2013). To this end, the Ukrainian legislation needs to implement the requirements of the EU directives and regulations, at least 80% of the current European standards, plus to choose or form an effective business model of interaction. Therefore, the improvement of the business model of the enterprise, which will be comprehensive, and therefore aimed at the formation of a quality management system, is a guarantee of the ability of the organization to produce and supply products stable, which corresponds to the European standards and becomes a priority. The development, implementation and maintenance of the business model in the state of capacity are one of the strategic directions of the business entities, as it should significantly increase their efficiency, economic efficiency and competitiveness on the world market (Zhi and Shoujian, 2014).

### ***3.4 The Benefits of Implementing European Standards in Ukraine at Micro, Meso and Macroeconomic Levels***

Ukraine pays great attention to the implementation of the requirements of international standards, as this is one of the conditions for joining the European Union. Besides when forming new ones or using existing business models at the enterprise, we consider it appropriate to take into account relevant approaches (Bebiakova, 2016). The business model should be considered as a managerial concept on how to create value for customers through the harmonization of standards and increase the value of the enterprise. In our opinion, such a combination of cost and value-added approaches to business modelling will enable us to accelerate the process of harmonization of standards in our country, which in the strategic perspective will receive from it such advantages (Shulgina, 2016):

- at the micro-level, the standards will most effectively promote the active introduction of innovative technologies, the economical use of raw materials and materials, extension of the shelf life, etc.;
- at the meso-level introduction of standards at enterprises will have a direct impact on the industry, as it will increase the competitiveness of enterprises, enlargement the number of investments in production, more efficient use of available resources, raise the attention to the ecological component, etc.;
- at the macro level, the augmentation in the number of certified enterprises in accordance with international standards should facilitate trade in the world market, improve the image of the state, develop the standard of the population's living and strengthen food security, etc. (Figure 1).

**Figure 1: The Benefits of Implementing European Standards in Ukraine**

Source: own elaboration (2017) on the base of (Ekonomichna Pravda, 2016; Potapenko, 2012)

#### 4. Conclusion

Given the integration intentions of Ukraine, harmonization of domestic standards with European in the fields of product quality, marketing standards and service standards is relevant. In harmonizing standards, Ukraine must coordinate its actions with the global goals of developing standards in the European Union.

In particular, the achievement of the first global goal – the formation of an open and competitive economy – requires the preservation, encouragement and support of human resources; developing information and communication technologies and increasing the size of the innovation market.

Objectives to achieve the second global goal – the development of a single market and the provision of quality food products to society – is the maximum orientation of enterprises to comply with EU standards; the positioning of their products in accordance with the ratio in the "price-quality" system adopted on European markets; creation of a multifunctional integrated communications system to inform producers about potential markets and consumers about diverse product manufacturers.

The third goal - the creation and use of effective business models, as well as their alignment with the processes of standardization of products and enterprises in general - requires the combination of value and value-added approaches to business modelling.

From the introduction of European standards in Ukraine, benefits will be gained on the micro, meso and macroeconomic levels of public life.

### **Abstract**

*Security environment of Europe and its neighborhood has undergone permanent erosion in recent years. Terrorism, illegal migration, failed states, civil wars in the neighborhood of the European Union (EU), as well as tensions with Russia are just some of the challenges for European security. Fortunately, more efforts has been done in the field of defence in the last two years than in the past twenty years. As a consequence, actions undertaken by European decision makers are heading towards creation of a European Army. The paper presents arguments for and common obstacles regarding creation of an European Army. Then discusses main activities inside the Common Security and Defence Policy which have triggered crucial actions leading to future building of a European Army. Finally, there is an answer to the question about rightness of such an initiative and general conclusion suggesting an increase of efforts by the EU member states in the field of defence rather than building common armed forces.*

**Keywords:** *Common Security and Defence Policy, European Army, European Defence Fund, European defence union, Permanent Structured Cooperation*

**JEL Classification:** *F50, F55, G20*

### **1. Introduction**

This type of wording of the question, as in the title of the article, provides the possibility to give a simple answer – “yes” or “no”. Unfortunately, in the case of a question about the need to expand the European structures with common armed forces, the answer is not so unequivocal. This results from the fact that the subject idea will have its supporters, as well as opponents, who will provide the appropriate arguments. It should be clearly emphasized that building European defence capabilities is crucial, even required in the face of emerging new challenges in the sphere of European (and not only) security. However, each action should be deliberate, therefore building common European armed forces must be based on foundations that all European Union (EU) Member States will identify with. Meanwhile, even now at the stage of free discussion, there are many discrepancies between European countries regarding the ideas for building join European army. Thus, it is justifiable to ask a question about the validity of building European armed forces and to seek answers to what is actually hidden behind the expression “European army”. Perhaps, there is no need to create another structure, which will be ineffective in the scope of threats that EU is currently facing and threats that it will be facing in the future. Perhaps, it will be sufficient to deepen cooperation between Member States using the existing tools in the field of security and defence. On the other hand, maybe the creation of a common European army will be an impulse that will lead EU to autonomy in the field of security and defence.

## 2. Acceleration of Activities in the Framework of Common Security and Defence Policy

EU's security and defence policy has been developed since the 90s of the last century. Since the Treaty of Lisbon has entered into force in 2009, it has been known as the Common Security and Defence Policy (CSDP). In the initial period, no significant actions were undertaken in order to develop the CSDP, despite the political and institutional development potential contained in the treaty provisions. Previous EU's activity in the context of security and defence was mainly focused on crisis management, based on the civilian and military capabilities of the Member States. Lack of own command structures and failure to use the potential of European rapid reaction forces (battlegroups) in crisis management contributed to the emergence of opinions regarding ineffectiveness of EU's actions in the field of defence and security, despite the fact that it implemented low-intensity operations in its immediate vicinity (Kaňa, Mynarzová, 2016).

2016 should be recognized as a crucial year in the context of development acceleration of the CSDP, aimed at creation of the European Defence Union, in which three major factors influenced the current activities associated with development of the EU's defence capabilities. These include: the referendum deciding on the United Kingdom's exit from the EU, the victory of Donald Trump in the American presidential election, which increased the uncertainty about Euro-Atlantic relations, and the adoption of *A Global Strategy for the European Union's Foreign And Security Policy (Shared Vision, Common Action: A Stronger Europe)* by the European Council.

Results of the referendum deciding on the United Kingdom's exit from the EU became an impulse for closer cooperation between Germany and France, especially in the field of defence, which was recognized by both countries as one of the three areas of deepening European integration. Paradoxically, Brexit may be considered to be a factor positively influencing the development of CSDP, because there is no longer a country within the EU that would inhibit the integration in the field of security and defence, and due to that fact the institutional strengthening of the CSDP is possible. However, it is necessary to note that defence capabilities of the United Kingdom must be compensated within the EU (Miszczak, 2017).

The second factor that accelerated the work of Europeans on defence policy was the U.S. presidential election won by Donald Trump. Until now, the Euro-Atlantic ties were a natural element of foreign policy, including the defence alliance, for the subsequent presidents of the United States. President Trump, during the election campaign, did not articulate this in a clear and obvious way, instructing the European elites about building defence capabilities on their own and about increasing defence spending. His words about the "obsolete NATO", spoken during election rally in the state of Wisconsin (The New York Times [online], 2016), must have caused concern among European allies, especially those from the eastern flank of NATO. This approach provoked discussions among European allies about becoming independent of United States in the area of defence capabilities, including the creation of new structures. In other words, based on anti-American public opinion in Western Europe, a mobilization occurred in the scope of development of the EU's defence policy. On the other hand, there is a visible uncertainty of some EU countries regarding the actual further commitment of the United States in the scope of ensuring security for Europe.

The third factor, which provided and provides legal framework associated with the EU's defence policy, refers to the adoption of *A Global Strategy for the European Union's Foreign And Security Policy* by the European Council in June 2016, which was prepared by the High Representative for Foreign Affairs and Security Policy – Federica Mogherini.

Failure associated with the implementation of previous security strategy from 2003 (European Council [online], 2009) resulted in the fact that the provisions of current strategy are less ambitious and more pragmatic. This document, which determines objectives and ambitions of the EU in the scope of security and foreign policy, focuses on the implementation of more realistic and pragmatic objectives mainly associated with security of the Member States.

Greater contribution to the European security should be expressed in five types of activities: security and defence, anti-terrorism, cyber security, energy security and strategic communication (information security). The North Atlantic Alliance is indicated as a collective instrument and guarantor of security of the Member States, with which the EU will closely cooperate. At the same time, the EU must deepen its cooperation with NATO, while maintaining the decision-making autonomy of both organizations. As for the other areas, all of them remain significant: in the shorter perspective – anti-terrorist activities are crucial, while in the longer perspective – cyber security is essential. In the scope of energy security, the EU could be a very effective strategic entity, but in practice it still does not play such a role. In the context of information security, the EU is losing the confrontation with Russia within new hybrid cold war (European Union External Actions Service [online], 2016).

It is also in the EU's interest to invest in vitality (endurance), i.e. sustainable stability of countries and societies in the east – to Central Asia, and in the south – to Central Africa, which is understood as the ability of countries and societies to reform themselves, including overcoming and reconstructing after crises. Important factors that increase strategic vitality of the EU's surroundings include expansion policy, neighbourhood policy and migration policy. In accordance with provisions of the EU's global strategy, it will invest in prevention, resolution and stabilization, avoiding premature exclusion from operations, when a new crisis breaks out somewhere. The EU will also support the building of regional systems of international order, also in the most disorganized and fragmented areas (European Union External Actions Service [online], 2016).

In a geographical context, the global strategy focuses on the extended region, which covers Eastern Europe with its Central Asian extension, as well as the Mediterranean and Central African areas. Thus, the EU no longer has the ambition of being a global actor in the structures of international order. Moreover, the document determines specific scenarios and perceptions of threats, which include change in the context of European security, caused by the aggression of Russian Federation against Ukraine. The Russian violation of international law and the illegality of annexation of the Crimean peninsula is clearly emphasized (European Union External Actions Service [online], 2016). The strategy also articulates other threats associated with the Russian activity: disinformation activities associated with military threats and hybrid activities aimed at internal political methods of destabilizing other countries. It also refers to previous threats, such as transnational terrorism and those threats that more and more clearly can destabilize individual countries – related to cyber security and energy security, organized crime or climate change. The strategy emphasizes that EU's internal security is directly linked to the external security, hence the fight against terrorism or proper migration policy may be crucial. This document very strongly articulates that the Member States must provide each other with support, as well as solidarity, and that assumptions of the strategy must be actively implemented, including the strengthening of structural cooperation of the states (Koziej, 2017).

Analysis of provisions of the EU's global strategy begs the question, whether this subject document includes any references to the need to create a European armed forces, which would be a tool to counteract the identified threats. It turns out that there are no direct references. Nevertheless, the nature of identified threats (at least some of them) and the need to implement the objectives of the European global strategy lead to the ascertainment that the EU must have

appropriate capabilities in this regard. Undoubtedly, some of them include capabilities in the field of security and defence, however it does not mean that there is a need to create common European armed forces.

### **3. Initiatives Contributing to a Common European Armed Forces**

European Community's activities associated with the acceleration of CSDP development should be linked to the meeting of EU leaders in Bratislava in September 2016, because they provided a formal impulse for the working out of specific decisions by Member States and the European Commission. During the informal summit of 27 Member States, a plan was adopted, which announced that one of the EU's priorities for the coming months will be strengthening of EU's cooperation in the field of external security and defence (European Council [online], 2016). Directions of development of the EU's security and defence policy, adopted by the European Council in December 2016, are based on the EU's global strategy and they focus on three strategic priorities: responding to external crises and conflicts, building capabilities of the partners, and protecting the EU and its citizens (European Council. *European Council meeting...* [online], 2016). Annual works resulted in initiatives in six key areas, which in the future may lead to the creation of a European Defence Union, and they certainly create a new quality of CSDP.

In the area of improvement of crisis management structures, the Military Planning and Conduct Capability (MPCC) was established, which has the purpose of improving the functioning of EU's crisis management structures. MPCC will function within the European Union Military Staff, which is a part of the European External Action Service, and it will be responsible for coordination of currently conducted training operations in Mali, Somalia and Central African Republic (European Union External Actions [online], 2017).

In the area of strengthening the EU's rapid response instruments, it was agreed that the Member States will jointly finance the use of battlegroups. The main source of financing, which will be implemented centrally, will be the Athena mechanism. The European Union battlegroups constitute rapid reaction forces, but in practice they have never been deployed in order to solve any crisis. The problems of political, technical and financial nature always stand in the way. Athena is a mechanism for financing common costs associated with the EU's military operations conducted under the CSDP (European Council [online], 2015). It is possible to finance the common costs of EU's military operations and the costs of individual countries, including accommodation, fuel and analogous expenses associated with the national contingents.

In the area of expansion of the military capabilities, coordination activities were undertaken in the form of introduction of the Coordinated Annual Review on Defence (CARD) mechanism. This will allow to achieve a better orientation at the EU level regarding spending, national investments and research in the field of defence (European Defence Agency [online], 2017). Consequently, it will increase transparency and it will politically articulate European defence capabilities. Whereas in the substantive context, it will allow to properly estimate shortages and it will enable deeper defence cooperation, as well as more coherent approach to the planning of defence spending, which are currently in the domain of individual Member States.

In the area of military-technical cooperation, which so far should be recognized as unsatisfactory, the breakthrough decision was establishment of the European Defence Fund (EDF) in June 2017, which will probably accelerate the integration processes in the scope of spending used for armament purchases (European Commission [online], 2017). This fund should help the Member States to cooperate, as well as develop and acquire key defence

capabilities. European decision-makers do not hide the fact that EDF's objective is also to become independent of the U.S. military capabilities and thus increase strategic autonomy. The key priorities include: unmanned aircraft systems, in-flight refuelling, satellite communication and cyberspace capabilities. Without going into the mechanisms of EDF's operation, it should be pointed out that it may be an opportunity for the development of modern technologies, which will result in specific military capabilities in the future.

In the context of creation of a common European army, it is necessary to recognize the decision made on 11 December 2017 regarding establishment of the Permanent Structured Cooperation (PESCO) as crucial. Such possibility is provided by art. 42, section 6 and art. 46 of the Treaty on European Union and Protocol No. 10 on permanent structured cooperation (European Union External Actions Service. *Permanent...* [online], 2017). It provides for close cooperation of a group of the Member States in the field of security and defence. A fixed framework of cooperation will allow Member States, which have the will and capabilities, to jointly develop defence capabilities, invest in the same projects and increase contribution and operational readiness of their armed forces. PESCO is supposed to be correlated with the activities undertaken within CARD and EDF. The possibility of acquiring critical capabilities, uniform for all EU Member States is indicated, and thus acquiring a common type of armaments and military equipment (e.g. European unmanned aircraft systems, ships, tanks, etc.). Consequently, it would enable the development of joint formations of the land forces, naval forces or air forces (Koziej, 2018).

#### **4. Arguments for and Against a European Army**

The above-mentioned initiatives provide a new impulse for development of the EU's defence capabilities and as a consequence – also for the creation of a European armed forces. The initiative to create a European army has its supporters, as well as opponents. The basic argument in favour of the creation of EU armed forces is the deepening of integration between Member States in the field of defence. It should be emphasized that despite legal possibilities, the defence domain has never been a priority in the context of European integration. Consequently, the building of defence capabilities, among others through the establishment of European army, is supposed to contribute to becoming independent of the United States, and thus it is supposed to contribute to strategic autonomy of the EU (Demetriou, 2016). Proponents of the establishment of common European armed forces also point to the fact that the EU will gain capabilities in the “hard power” area, which it has not had so far, despite the functioning (theoretically) of battlegroups or rapid reaction forces. Thus, the EU's role in the international arena may increase in the context of involvement in solving difficult crisis situations or even conflicts. As positive, in the context of the above-mentioned initiative, should be also recognized the improvement of cooperation between Member States, which may be a way to reduce the costs of maintaining units or introducing new types of armaments. On the other hand, it is worth to mention that concepts associated with international cooperation and sharing of capabilities already function in the EU, e.g. Pooling & Sharing initiative, bilateral and multilateral agreements between European partners in the scope of defence. Enthusiasts of the creation of European army also maintain that its capabilities would be complementary in relation to the North Atlantic Alliance and this would allow to alleviate the burden of NATO. At the same time, they indicate that European armed forces should take care of the protection of EU's borders, thus narrowing the scope of possible involvement (Faleg, 2017).

However, in the public debate, the prevailing views articulate doubts or even negate the need to create a European army. Firstly, such views indicate that there is no political will of all EU

Member States. This results from the diverse perception of security sphere in the EU itself. For example, European army seen through the eyes of the eastern flank states is another tool ensuring collective defence. On the other hand, the south of Europe perceives this initiative as a tool that will stop migration and stabilize African countries. The caution of NATO's eastern flank countries primarily results from the concerns associated with duplication of efforts related to the maintenance and development of specific military capabilities, which in consequence may lead to a weakening of the Euro-Atlantic ties and NATO itself. These countries point to the fact that EU's engagement, resulting from provisions of the global strategy, is still mainly focused on crisis management. Thus, these countries are afraid that collective defence may be put aside. Consequently, initiatives and programs associated with the development and building of capabilities will not focus on real defence capabilities of the countries, preferring the "soft" skills (Gotkowska, 2017). In other words, EU Member States are too divided to speak with one voice on such a sensitive issue as military operations. At the same time, the deepened integration of selected states forming the core of defence may contribute to the functioning of many defence speeds in the EU, which in itself will be unfavourable.

It also seems that the value of EU's military power would not be heavy; such an army would be too small to play a serious role. Experiences from Libya have shown that even such militarily significant countries as France and United Kingdom are unable to carry out a large operation without incurring major costs by the United States (Zieliński, 2014).

There are also doubts regarding unclear financing issues of the subject initiative. EU armed forces would be probably expensive and would require large amount of resources in order to form, equip and maintain them. In the situation of insufficient defence spending in the entire Europe, this would be carried out at the expense of national armies that can be used in NATO operations.

The biggest concerns regarding the ideas of European army result from the lack of clarity about the scheme of making political decisions concerning its use. As is known, European institutions exhibit a trend of exerting open pressure on individual states and deciding against the will of some of them, e.g. by majority voting, which was evident during the migration crisis. Similar questions appear in the context of command of European armed forces, i.e. questions about the effectiveness (political and military) of managing such new creation, especially taking into account that Member States are reluctant to delegate the right to make decisions about using their own armed forces to other organs.

## **5. Conclusion**

There is no doubt that any attempt to tighten military cooperation in Europe is worth considering. This also applies to the possible creation of European armed forces. However, it requires a systemic approach based on strategic goals of functioning of the European Union, including in the area of defence. Appearing concerns of individual countries regarding their sovereignty, lack of mutual trust, as well as technical and bureaucratic obstacles in the EU have negative impact on integration processes in the area of building defence capabilities. It seems that striving to achieve strategic autonomy of the European Union in the field of defence requires resolving of several key issues. Firstly, it is necessary to develop EU's catalogue of threats, which will be just as important for the eastern flank states as for the southern flank states and other Member States. Various perception of security in the European Union is not conducive to building EU's defence capabilities. Secondly, it is necessary to harmonize defence planning and development of EU's defence capabilities. It must be clearly emphasized that it should be carried out in a complementary manner in relation to the North Atlantic

Alliance, in order to not to duplicate efforts in this area. Thirdly, the potential contained in bilateral and multilateral cooperation between Member States in the field of defence must be activated to a greater extent. Fourthly, it is necessary to implement mechanisms that will improve decision-making process at the strategic level and it's also necessary to strengthen direct cooperation with the North Atlantic Alliance.

It seems that the desired direction of changes should be the further tightening of military and industrial cooperation, including the creation of command structures, joint units or realistic standards of interoperability. However, in the author's opinion, it should not be equivalent to the subordination of national forces to European institutions. The format of close cooperation, without giving away the control over even a part of the national armed forces, provides greater possibilities of cooperation with non-EU countries, including United Kingdom or United States. Undoubtedly, the groundbreaking decisions that have been made by the European community in 2017 in the scope of defence accommodate the above-mentioned observations. Special attention should be paid to the initiatives of PESCO and EDF, which are an opportunity for real strengthening of combat capabilities, especially in the cases, in which the majority of EU countries are too weak individually. Also, it should be added that NATO, differently than in the past, favourably refers to the EU defence integration, believing that in its present form it is not a competition and it can bring benefits (Smith, Gebhard, 2017). Primarily, through better spending and non-duplication of military capabilities, as well as through activity in places, in which both NATO and USA usually do not get involved.

To sum up, the deepening of cooperation in the field of defence between EU states is necessary. However, it should be implemented with respect to the sovereignty of individual states and taking into account their real capabilities, in order to avoid the functioning of Europe of many speeds in the scope of security and defence.

### **Abstract**

*The key features of current global developments in international markets include an increasingly challenging competitive business environment in which effective positioning of companies becomes one of the preconditions for achieving and sustaining a long-term competitive advantage, thereby application of principles of excellence in business strategies of companies is a necessity. The paper will be focused on the review of the scientific theoretical background of the issue of achieving excellence, on the analysis of the EFQM model as an internationally recognized, universal and most widely used tool for achieving and simultaneously evaluating Business Excellence in EU countries in comparison with other European countries. The paper will be also focused on comparison of EFQM award winners in Slovakia and the Czech Republic.*

**Keywords:** *application of the EFQM excellence model in the EU, business excellence, competitiveness*

**JEL Classification:** *D21, F47, L21*

### **1. Introduction**

The current changes in the market environment are so quick and fundamental, that the earlier proven management methods are very quickly outdated and replaced by newer – more innovative ones. The influence of globalization, openness of the European market and increasing competitive pressures cause in enterprises need to streamline a number of processes as national or territorial views on achieving success of companies' are no longer sufficient (Čemerková, 2016). From the perspective of strengthening competitiveness and growth within the global impacts of business activity (Adámek, 2016), companies must acquire and apply entirely new approaches to mobilizing their tangible and intangible assets. Therefore, business success in international perceptions these days depends on the effectiveness of the system of management and on application of the principles of exceptionality – excellence in it. The goal is to get ahead of the competition and to achieve by this a significant competitive advantage in the markets. It is a search for new market opportunities, an effort to achieve higher economic effects through innovative steps used in business strategies. From this point of view, it is clear that businesses which want to challenge the new conditions and create an advantageous position in a globalized world for itself should fundamentally change their perceptions of business, as the pursuit for the new business concepts is no longer an option, but it is necessity now.

Based on theoretical views on possibilities of achieving the exceptionality of companies by increasing the overall efficiency of their business up to the highest level of excellence, the aim

of this scientific paper is to identify internationally recognized and in individual European countries accepted ways of assessment of the quality of business strategies. At the same time, the goal is to analyze the established Business Excellence evaluation standards by applying the EFQM model in European countries, focusing on EU member states and the ways of assessing company exceptionality as well as the results of these assessments in case of firms operating in the Czech Republic and the Slovak Republic.

### ***1.1 Theoretical Basis of Achieving Company Exceptionality – Business Excellence***

According to Porter, L. J. and Tanner, S. J., the assessment of Business Excellence status or business exceptionality is an essential part of learning and measurement of process which enables organizations to identify strengths and opportunities for improvement while developing cutting-edge programs which are monitored in an arranged way. Self-assessment is a complex, systematic and regular assessment of the organization's activities. These types of business or organizational assessment are one of the most powerful tools available (Porter, Tanner, 2004).

Peters, T. and Austin, N. perceive excellence as a result of the following critical factors of success (Dahlgard-Park, Dahlgard, 2006): implementing people – employees; permanent customer care; continual introducing of innovation; management – supervision that combines the above mentioned 3 factors (employees, customers, innovations) at all levels of the organization.

Slovenian authors Štok, Z. M. ; Markič, M. ; Bertoneclj, A. ; Meško, M. define excellence as improving quality. They perceive the excellence as a high quality, even as the highest possible quality. According to their views, excellence is a stimulus and a driving force of development, quality and personal, collective and organizational growth. It is an intense activity that reflects in the behavior of each team member which achieves excellent results. Excellence is formed gradually, thanks to mental well-being and harmony. (Štok et al [online], 2010).

Croatian economists Pozega, Z.; Crnkovic, B. and Udovicic, A. are of the opinion that Business Excellence represents a high standard of quality at all levels of the organization. As a truly exceptional organizations they consider those which have adopted the Business Excellence concept as an important tool for future development and have perceived quality as an integral part of the whole organization. Business success is defined and measured by various qualitative and quantitative indicators, BE being a form of qualitative measurement of organizational success. This concept is defined by the principles of focusing on results, paying attention to the customer, employee development, continual education process, introduction of innovations, development of business partnership relations and corporate social responsibility. A number of successful organizations have already adopted the concept of quality achievement and evaluation, and have also been awarded by commissions which evaluate compliance with nationally and internationally recognized Business Excellence models. The above-mentioned Croatian authors consider Business Excellence as the most powerful tool for achieving competitive advantage for companies, while overall quality management is the way to ensure the boost of excellent results which are recognized by many world companies. The basic idea of BE's approach is that quality can not be focused solely on products and services. Quality has to be incorporated into the management of its overall business strategy and should be a core value for all management processes (Pozega, Crnkovic, Udovicic [online], 2014).

Zorkóciová, O. and Ďuranová, L. state that the achievement of the level of excellence of companies is associated with the ability to use the creative talents of managerial thinking. They perceive the excellence as ability of a company to generate profits while meeting the high

requirements of consumers. It means the realization of proper activities, at the right time, with the aim of ensuring long-lasting intentions of the organization (Zorkóciová, Ďuranová, 2015).

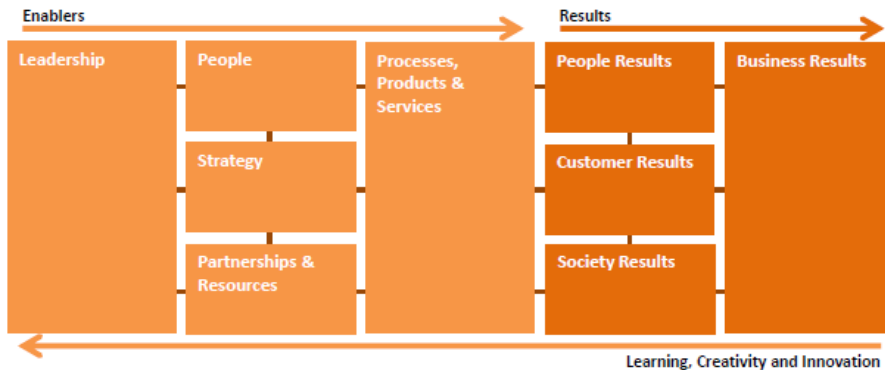

Nowadays, businesses face growing demands in the area of improvement of their performance and quality of their products. If businesses want to succeed in the markets with strong competitive pressure, they have to focus their attention on reaching the status of so-called excellence. One of the possible ways to achieve this status is constant – permanent introduction of innovations, which Jankal, R. emphasizes in his work. It is not just product innovations, but also innovations of business processes, marketing and organizational innovations, innovations in the field of human resources management, and so on. Constantly increasing customer requirements for products quality can be characterized by favoring innovations, stylish products which are sold at an affordable price and at the same time they are available on the market, products which are carriers of technological, economic and social progress (Jankal [online], 2014)

## **2. EFQM Excellence Model (Problem Formulation and Methodology)**

As has already been mentioned, the European companies operate in increasingly difficult and complicated conditions of development, such as dynamic processes of globalization, complexity and intensity of environment, new requirements and competitive intensity of competition (Barcik, 2016). The basic prerequisite for achieving and maintaining long-lasting competitiveness lies in the efficiency of business processes, with the international aspect of company success depends on the optimization of managerial guidance and the introduction of excellence in it. Practical and effective tools for achieving and assessing excellence today are excellence models that are involved in the constant development of all business processes in terms of the direction of corporate goals so as to ensure their continuous improvement and growth of competitiveness. The qualitative streamlining of management processes is covered in Europe by excellence model EFQM created by European Foundation for Quality Management (EFQM). The EFQM model is a managerial tool for increasing the competitiveness and performance of organizations. It serves to voluntary comparison of the nine criteria framework which can be implemented by any organization without distinction. In a simple way, it points to the tools and resources that management has at its disposal, making it easier to decide of using these resources to increase business efficiency. The EFQM excellence model points to the relevance of the relationship between the results and the sources and the comprehensive understanding of the interconnection of all the criteria of the organization.

The EFQM model deals with nine basic areas, which represent the main criteria for self-assessment. The first five of them assess the resources and tools the organization has at its disposal (leadership, policy and strategy, staff, partnerships and resources, and processes).

**Figure 1: The Structure of the EFQM Excellence Model**

Source: elaborated by authors according to EFQM [online], 2012

At first glance at the EFQM excellence model it is not visible that it allows to find resources to increase organization's performance, so it is recommended to evaluate individual criteria and the state of the organization. Although self-assessment may appear to be a simple and inexpensive alternative of an external evaluation of a company, it is a demanding process.

#### **Criteria of requirements (Zorkóciová, Škodová, Petriková, 2017)**

**Leadership:** The main subject of this criterion is of conceptual role of business leadership, which consists of two moments: development tendencies which are clearly defined by company leadership (politics, mission, vision, code of ethics, etc.); business leadership encourages and motivates all employees to achieve the set goals of the company. Management of change across the organization is implemented through a structured and systematic way and includes employee behavior that is linked to the company's values, policy, and interests.

**Strategy:** The essence of this criterion is to deal with the way of implementation of mission and vision through a clearly defined strategy of interested parties and with support of relevant policies, plans, tasks, goals and processes.

**Staff (people):** Based on this criterion, the way of organization's management, development and providing access to knowledge is identified. It allows a more detailed perception of workers' potential (individual, team and company level) and of activities supporting the planning process of the effectiveness of own policy, strategy and processes.

**Partnerships and resources:** The purpose of this criterion is to support policy, strategy, and processes efficiency by planning and managing the company's internal resources. It also assesses the extent to which the company manages its resources efficiently and effectively.

**Processes, products and services:** Past experience confirms that all activities in a company must follow certain sequence from the beginning to the end of its course. Individual processes are assigned to their keepers, and their improvement is based on the active day-to-day involvement of all employees to satisfy and provide higher value to customers and to other interested parties. The work of management is effective when there is continuous measurement and feedback, which provides benefits in relation to the mission of the organization.

**Results criteria (Mad'arová, 2007)**

*Results in relation to customers:* An integral part of all businesses is the direct measurement of their customers' satisfaction, including their loyalty, overall image, sales support, products and services.

*Results in relation to workers:* The important role of all businesses is to record the results in relation to employees which are concerned with their motivation, engagement and with satisfaction in the company. These are, above all, the conditions of career development and personal skills as well as the conditions of their employment, remuneration, or work environment.

*Results in relation to the company:* Through this criterion more detailed information are determined about company's perception of the quality of life, the environment, the protection of global resources, and the use of internal indicators of business effectiveness. Equally important is mutual communication with authorities and bodies that perform the regulatory function.

*Key results:* They represent what the business achieves compared to the planned performance. Based on the purpose and objectives of the organization, some measurements included in key performance outputs (financial or non-financial outputs) can be applied to critical performance indicators. They may also be related to key processes parameters in a company (e.g. market share, productivity, production cycle, time of response to a demand, accessibility of information, failure rate, innovation rate, patents, licenses, etc.). Each criterion is further subdivided into several of sub-criteria which are assessed in selected excellence models with the aim to improve performance and increase the competitiveness of companies.

In the next part of the paper, we analyze the use of an internationally recognized EFQM model in comparison to other models or approaches to evaluation of achieving of company excellence in EU Member States as well as in other European countries, and the entities competent to carry out these processes. We also will focus on evaluating the achievement of the highest degree of excellence by applying the EFQM model through comparison of companies operating in the Czech Republic and the Slovak Republic.

**3. Application of the EFQM Excellence Model in the EU, Focusing on the Czech Republic and the Slovak Republic (Problem Solution)**

The way to assess the achievement of business excellence varies from country to country. The reason is the possibility of applying different models and approaches, which are often based on differences in culture, economy, recognized values, standards, managerial approaches, and so on.

An analysis of the company's excellence assessment shows that all EU Member States except Bulgaria, Cyprus, Croatia and Malta are using internationally recognized excellence models in this process.

The EFQM model is thus applied by a large majority of EU countries, but some of them also use other models of excellence assessment, e.g. Hungary applies the EFQM model and the national model based on the Deming Prize. They are a different awards covered by different organizations. In Poland, companies can apply for two different awards through the EFQM model. Ireland favors the EFQM model as a valuation tool along with the national model based on the Baldrige model, but they are two different prizes. Constituent countries of the United Kingdom, such as Northern Ireland, Scotland and Wales use the EFQM model. In Sweden, it is possible to apply up to 3 models, namely EFQM, Baldrige and the national model, but

companies run for the same one award. Greece uses its national model and national model based on EFQM to try to achieve various awards covered by different organizations. Spain and Luxembourg prefer their national model, so do Slovakia, France and the Netherlands, but the basis of this national model is the EFQM model.

Countries that are not members of the EU, such as Russia, Ukraine and Switzerland, use EFQM models as well, while Norway and Iceland have national models. The difference is only that the Norwegian model is based on the EFQM model and in the case of Iceland this model is based on combination of the EFQM and the Baldrige model.

A specific case is the island of Aruba, the Caribbean island, which belongs to the Kingdom of the Netherlands, but is geographically located in Latin America. As Aruba uses the national model based on the Baldrige model (typical for the US), it can be said that the geographic aspect prevails in this case (Nist [online], 2010).

The National Quality Award is the highest award which can be achieved by organizations in the Slovak Republic (since 2000) and in the Czech Republic (since 1995) in the area of quality management systems. The main goal of the National Quality Award is to start a journey to excellence, or path of innovations and improvement of all approaches (activities) of organizations in the 21st century. The award is based on the application of quality models which are used in similar competitions in other EU countries and outside the EU.

The National Quality Award is awarded in two segments – in business and public sector. While the evaluation in the business sector is based solely on the EFQM excellence model, in the public sector organizations can use both the EFQM model and the specific CAF model, a quality model for public administration organizations. The Czech Republic, in addition to the Excellence Program (based on the EFQM model) and the CAF program, uses in both sectors also simplified versions of the EFQM Excellence Model, namely Start, Start Europe and Start Plus.

In our paper, within the EU we focus on the evaluation of corporate excellence in the Slovak Republic and the Czech Republic. The basis of the comparative framework for these countries is EFQM excellence model, which shows slight differences in the given evaluation procedures (table 1).

**Table 1: Excellence Model and its Degrees of Appreciation in the Slovak Republic and the Czech Republic**

Slovakia –EFQM Excellence model		Czech Republic – Excellence Program (EFQM)	
200 – 300 points (p)	Appreciation for participation of the organisation in the competition	200 – 299 p	Perspective organization
301 – 400 points	Appreciation for improving organization performance	300 – 399 p	Successful organization
401 and more p	Award-winning finalist	over 400 p	Excellent organization Recognition for excellence (4 to 5*)
Minimally 450 p	National Award Winner		

Source: elaborated by authors according to Únms [online], 2018 and Sok [online], 2016

In the following table, we list the winners with the highest business excellence awards in the Slovak Republic and in the Czech Republic in 2014 – 2017 (data for 2017 are not officially available in the Czech Republic). In order to compare the achieved results in the area of business excellence evaluation in the Slovak Republic and the Czech Republic, due to a partially different methodology, we will compare „National Award winner“ in the Slovak Republic with „Excellent organizations with 5\*“ in the Czech Republic and with an „award-winning finalist“ level in the Slovak Republic we will compare „excellent organizations with 4\*“ in the Czech Republic.

**Table 2: Awarded Companies Based on the EFQM Excellence Model in 2014 – 2017**

Year	Slovakia	Czech Republic
	<b>National Award Winners:</b>	<b>Excellent organizations (Recognition for excellence 5*):</b>
2014	HANIL E-HWA AUTOMOTIVE SLOVAKIA (BS)	Hyundai Motor Manufacturing Czech (BS)
	I.TRAN (BS)	AHOLD Czech Republic (PS)
	Social service facility (Sunny house) (PS)	Secondary vocational school of Multimedia and Promotion (PS)
2015	Slovak Information and Marketing Company (BS)	AHOLD Czech Republic (PS)
	Faculty of mechanical engineering – Technical University of Košice (PS)	
2016	Kia Motors Slovakia (BS)	Miele technology (BS)
2017		Data is not available
<b>Year</b>	<b>Award-winning finalists</b>	<b>Excellent organizations (Recognition for excellence 4*):</b>
2014	Faculty of Management Science and Informatics – University of Žilina (PS)	Liberec Region (PS)
2015	CEIT Biomedical Engineering (BS)	Kermi (BS)
		Faculty of Agriculture – University of South Bohemia in České Budejovice (PS)
2016		Kaufland Czech Republic (BS)
2017		Data is not available

Source: elaborated by authors according to Únms [online], 2018 and Sok [online], 2016  
 Explanatory notes: BS – Business sector, PS – Public sector

In 2014 and 2015, neither in Slovakia nor in the Czech Republic was awarded the title „Appreciation for improving organization performance“ or „Successful organization“. Eight organizations in the Czech Republic were in 2014 and 2015 in the program Start Plus, which is the simplified versions of the EFQM Excellence Model. In 2016 and 2017, no organization

applying EFQM model in Slovakia was awarded title „Appreciation for improving organization performance“, in the Czech Republic in 2016 the „successful organization“ became Population Protection Institute in Lázně Bohdaneč.

In 2014, only in the Czech Republic the public sector organization the Seniors' Home of Kdyně became a „prospective organization“. In 2015, the Hradec Králové Region was regarded as the „perspective organization“ in the Czech Republic. In 2016 and 2017, no organization in Slovakia was awarded an „Appreciation for participation of the organisation in the competition“ and no organization in the Czech Republic became „Perspective organization“ in 2016 (Únms [online], 2018 and Sok [online], 2016).

#### **4. Conclusion**

The principles of excellence extend the life-cycle of products through their constant improvement by using of cutting-edge technologies and by their innovations. The penetration to international markets, supported by the application of excellence in management, boosts the economic performance of enterprises and enhances their competitiveness. It reduces the cost of purchased inputs by actively involving a wider range of suppliers in the procurement and helps optimize corporate resources.

Based on an analysis of EFQM excellence model applications in European geographical area, it can be stated that it is most often used to assess the achievement of outstanding business results by companies not only in EU member countries, but also in general. The other forms or approaches in evaluation are only supportive and complementary to the model, and are used only to a very limited extent (whether it is the application of the most used model in the US – the Baldrige model, or the separate national models or assessment procedures). Also, in the Czech Republic and Slovakia, the basis for achieving and thus evaluating the level of company excellence is the EFQM model method, although, as we point out in our paper, we can identify slight differences in the procedures. There is, however, another question: to what extent the public – the end consumer – perceives the fact, if at all, that a firm has achieved a level of excellence. Or, this is reflected in the quality of products and services, and therefore probably in the interest of the public, but without awareness of achievements in Business Excellence. But this is already a subject for the analysis of another scientific paper.

## **Abstract**

*Concerning the significance of innovation in enhancing competitiveness of the European Union (EU) it is important to explore how the main drivers of innovation performance external to the firm, differ between the EU countries. In this regard the special attention was put on the Visegrad Group countries (V4). In the study a multivariate analysis and zero unitarization methods were applied. These methods allowed to analysis the differences between V4 countries in terms of human resources, attractive research systems and innovation-friendly environment dimensions. The study was based on data from the European Innovation Scoreboard 2017. The time period was 2009–2015. The results reveal, among others, the necessity to strengthen the actions enhancing the level of the main drivers of innovation performance external to the firm in the Visegrad Group countries. Such action may result in enhancing competitiveness of the European Union and fostering European integration processes.*

**Keywords:** *competitiveness of the EU, innovation drivers, the Visegrad Group countries*

**JEL Classification:** *O30, R11, O52*

## **1. Introduction**

Enhancing competitiveness of countries, regions and firms is the priority of the European Union (EU), leading to sustainable and inclusive growth of the EU Member States and to intensification of European integration processes. In this respect, the importance is put on innovation as the key factor of economic growth. The significance of innovation in fostering competitiveness of countries, regions and firms has been widely argued in the economic literature (see, e.g., Coenen *et al.*, 2017; Fagerberg, 2017; Barca, 2009) and is particularly highlighted in endogenous growth theory and knowledge spillovers theory. Therefore, the crucial is creation appropriate condition for innovation (see, e.g., Acs *et al.*, 2016; European Commission, 2017). In this context, the substantial are innovation drivers external to the firm.

Regarding the above, it is very important to check how the main drivers of innovation performance external to the firm differ between the European Union countries. Here, the paper the special attention puts on the group of Central European states. Thus, the aim of this paper is to explore how the main drivers of innovation performance external to the firm differ between the Visegrad Group countries (V4).

In order to achieve its aim, the paper is based on theoretical analysis of the problem concerning on a related literature review. The empirical data used in the study were gathered from the European Innovation Scoreboard 2017 (EIS). The time period is 2009–2015.

The paper is structured as follows. First part takes a glance at the literature on the main drivers of innovation performance external to the firm and presents the methodology. The following part presents the results. Last part provides the conclusions.

This study presents new insight on understanding the issues connected with the main drivers of innovation performance external to the firm. Zero unitarization method and a multivariate analysis were applied in order to identify the differences between the Visegrad Group countries, in terms of the main drivers of innovation performance external to the firm.

## 2. Problem Formulation and Methodology

Following the current state of literature on economic growth, innovation stimulates competitiveness of countries, regions and firms (see, e.g., Fagerberg, 2017; Acs *et al.*, 2016; Coenen *et al.*, 2017). Based on endogenous growth theory and knowledge spillovers theory, innovation strengthens competitive advantage and economic growth of countries, regions and firms (see, e.g., Acs *et al.*, 2016). With respect to the rank of innovation in fostering competitiveness, the crucial is creation appropriate condition for innovations. Here, the role of country and regional policy is essential. In this regard, countries and regions should build backgrounds for innovation and develop the network between, among others, universities, institutional environment, research organisations and firms (Fritsch and Storey, 2014; Martin, 2006). Hence, achieved cooperation will enhance competitiveness of countries, regions and firms (Zygmunt A., 2017). Following this, the European Union put special attention on creation the conditions for an innovation ecosystem (European Commission, 2017) as the core of competitiveness and integration processes. In this context, the role of social, economic and territorial conditions of regions and combination of endogenous and exogenous indicators of development are emphasised (see, e.g., Barca, 2009; Melecký and Staníčková, 2014). Thus, innovation emerge when conditions are continuously enhanced. In this respect the European Union puts the special concern on innovation drivers external to the firm, with emphasis on human resources, attractive research systems and innovation-friendly environment.

Considering human resources, a number of theoretical and empirical studies highlights their significance in competitive advantage of countries, regions and firms (see, e.g., Florida, 2014; Fritsch and Storey, 2014). Here, a wide body of empirical literature assessing the role of human resources formation (see, e.g., Coenen *et al.*, 2017). In this regard, the amount and structure of human capital is essential (Zygmunt J., 2017). Thus, human capital may impact, among others, on diversity management of firms (Maj, 2017) and their competitiveness. With respect to the importance of human resources as an innovation driver, the crucial is “the role of universities in building human capital” (Huggins *et al.*, 2008). Hence, attractive research systems is emphasised. Following this, research system provides knowledge necessary for fostering innovation and is treated as an important driver of innovation (Huggins *et al.*, 2008). In this context, the substantial importance is put, among others, on academic research and scientific publications as the core of creation new knowledge (see, e.g., Acs *et al.*, 2016; Martin, 2006). According to a number of studies, innovation drivers external to the firm, focused also on innovation-friendly environment (see, e.g., Coenen *et al.*, 2017). Here, the essential for enhancing of innovation are broadband penetration (European Commission, 2017) and opportunity-driven entrepreneurship (Fritsch and Storey, 2014) as the link between competitiveness of firms and competitiveness of countries and regions.

The importance of innovation drivers in enhancing competitiveness of the European Union requires undertake studies how the main drivers of innovation performance external to the firm differ between the European Union countries. In this regard, special interest was put on the group of Central European states. Therefore, the following hypothesis was posed: despite

belonging to the same group, the Visegrad Group countries differ in terms of the main drivers of innovation performance external to the firm.

The data of this study were gathered from the last report of the European Innovation Scoreboard 2017 (European Commission, 2017). In relation to the main drivers of innovation performance external to the firm, the EIS contains three dimensions regarding to human resources, attractive research systems and innovation-friendly environment (with data available for 2009–2015). These dimensions and their eight specific indicators stay in accordance with endogenous growth theory and knowledge spillovers theory. The special attention was put on data concerning the Visegrad Group countries: the Czech Republic, Hungary, Poland and Slovakia. The time period was referring 2009–2015. The descriptive statistics of diagnostic variables, comprising mean, standard deviation, minimum and maximum are presented in Table 1.

**Table 1: Descriptive Statistics of Diagnostic Variables**

Variables			Mean	St. Dev.	Min.	Max.
<b>Human resources</b>	$x_{1t}$	New doctorate graduates per 1000 population aged 25-34	1.35	0.70	0.60	2.40
	$x_{2t}$	Percentage population aged 25-34 having completed tertiary education	30.68	5.51	26.41	40.00
	$x_{3t}$	Percentage population aged 25-64 participating in lifelong learning	6.13	2.49	3.54	9.73
<b>Attractive research systems</b>	$x_{4t}$	International scientific co-publications per million population	351.01	108.69	204.67	508.95
	$x_{5t}$	Top 10% most cited publications	5.90	1.10	4.42	7.31
	$x_{6t}$	Foreign doctorate students	7.50	3.64	2.09	12.29
<b>Innovation-friendly environment</b>	$x_{7t}$	Broadband penetration	8.32	0.90	7.00	9.14
	$x_{8t}$	Opportunity-driven entrepreneurship	1.46	0.57	0.78	2.28

Source: own calculations based on data from the European Innovation Scoreboard 2017 (European Commission, 2017)

In order to empirically analyse how the main drivers of innovation performance external to the firm differ between the Visegrad Group countries, zero unitarization method and a multivariate analysis were applied. The combination of these methods allow to an analysis the differences between the European Union countries (Balcerzak, 2015) and “enables comparing the values of synthetic index for all years” (Balcerzak, 2015, pp. 191) and were used for each of the EIS innovation dimensions related to the main drivers of innovation performance external to the firm (human resources, attractive research systems and innovation-friendly environment).

Firstly, the normalisation of diagnostic variables was carried out. In this respect, on the base of zero unitarization method, a constant reference point (the range of the normalized variable) was calculated in compliance with the following formula (Kukuła & Bogocz, 2014):

$$R(X_{jt}) = \max_{it} x_{ijt} - \min_{it} x_{ijt} \quad (1)$$

Regarding that all diagnostic variables are the stimulants, to normalisation of diagnostic variables the following formula was used (Kukuła & Bogocz, 2014):

$$z_{ijt} = \frac{x_{ijt} - \min_{it} x_{ijt}}{\max_{it} x_{ijt} - \min_{it} x_{ijt}}, \quad (2)$$

where  $z_{ijt} \in [0,1]$ ; ( $i = 1,2, \dots, n$ ); ( $j = 1,2, \dots, m$ ); ( $t = 1,2, \dots, l$ )

Next, the synthetic measure was calculated according to the following formula (Balcerzak, 2015):

$$SM_{it} = \frac{1}{m} \sum_{j=1}^m z_{ijt}, \quad (3)$$

where  $z_{ijt} \in [0,1]$ ;  $SM_{it} \in [0,1]$ ; ( $i = 1,2, \dots, n$ ); ( $j = 1,2, \dots, m$ ); ( $t = 1,2, \dots, l$ )

Above procedure allowed to investigate how the main drivers of innovation performance external to the firm differ between the Visegrad Group countries.

### 3. Problem Solution

Table 2 to 4 provide a multivariate analysis of the main drivers of innovation performance external to the firm between the Visegrad Group countries. With respect to the human resources dimension, the results show that among the V4 countries, the Czech Republic distinguish relatively the highest level of new doctorate graduates, percentage population aged 25-34 having completed tertiary education and percentage population aged 25-64 participating in lifelong learning (Table 2). Such situation concerns the period 2009-2015 and should be treated as positive, especially in the context of enhancing competitiveness of country, regions and firms.

**Table 2: The Results of a Multivariate Analysis of the Main Drivers of Innovation Performance External to the Firm Between the Visegrad Group Countries – Human Resources Dimension (in the Period 2009-2015)**

2009			2010			2011			2012			2013			2014			2015

Legend: CZ – the Czech Republic, HU – Hungary, PL – Poland, SK – Slovakia.

Source: own calculations based on data from the European Innovation Scoreboard 2017 (European Commission, 2017)

In contrast, the results provide evidence about Hungary ranked in the last place in terms of human resources dimension (especially in 2009-2014). This situation should be treated as negative in relation to build a competitive advantage of country, regions and firms. Within the EU countries from the Visegrad Group, Poland and Slovakia highlighted relatively the similar level of the main drivers of innovation performance external to the firm, related to human resources dimension (especially in 2009-2011, 2015). In line with the obtained results, the

level of indicators of human resources in these countries are in between the Czech Republic and Hungary. The results also reveal in Poland (in 2012-2014) the increasing level of new doctorate graduates, percentage population aged 25-34 having completed tertiary education and percentage population aged 25-64 participating in lifelong learning. This implies improvement of the main drivers of innovation performance external to the firm, which may result in enhancing Polish competitiveness.

Following attractive research systems dimension, the results indicate relatively high diversity between the Visegrad Group countries (Table 3).

Source: own calculations based on data from the European Innovation Scoreboard 2017 (European Commission, 2017)

According to the obtained results, in terms of international scientific co-publications per million population and top 10% most cited publications and foreign doctorate students, the Czech Republic outstand noticeable from the group of the EU countries from . This situation was seen in 2009-2015. It proves that the Czech Republic constantly improved the attractiveness of research system, which may enhance competitiveness position of country, regions and firms. Regarding Hungary and Slovakia, the obtained results highlight relatively high level of indicators connected with attractive research systems dimension. This should be treated as positive in regard to maintain and enhance the capacity to competitive advantage of country, regions and firms. On the other hand, among the other Visegrad Group countries, Poland ranked in the last place in the field of international scientific co-publications per million population and top 10% most cited publications and foreign doctorate students. This situation, in relation to relatively lack of enhancement the level of attractive research systems indicators should be treated relatively negative in relation to enhance competitiveness of country, regions and firms.

Concerning innovation-friendly environment dimension, the results imply relatively high rank of Hungary among the other Visegrad Group countries (Table 4). In compliance with the obtained results, Hungary distinguished relatively the highest level of enhancement of broadband penetration and opportunity-driven entrepreneurship (in 2009-2015). Such situation should be treated as positive in relation to build a competitive advantage of country, firms and regions. Among the other V4 countries, the Czech Republic and Poland highlighted relatively similar, high level of the indicators connected with innovation-friendly environment dimension. This should be treated as positive in context of competitiveness improvement.

Legend: Like in table 2.

Source: own calculations based on data from the European Innovation Scoreboard 2017 (European Commission, 2017)

Within the EU countries from the Visegrad Group, the level of enhancement of broadband penetration and opportunity-driven entrepreneurship in Poland differed significantly from the rest of V4 countries.

#### 4. Conclusion

The results reveal, that in terms of the main drivers of innovation performance external to the firm, the Visegrad Group countries differ from each other. In this respect, relatively the highest level of indicators of human resources and attractive research systems dimension distinguished the Czech Republic. This situation, in relation to the relatively high level of indicators connected with innovation-friendly environment dimension, may influence on the enhancing abilities of the Czech Republic to adaptation to dynamic environment and, in consequences, on enhancing competitiveness and European integration processes. The results show relatively high level of the main drivers of innovation performance external to the firm in Slovakia and Hungary. This implies positive backgrounds for enhancing competitiveness of country, regions and firms. On the other hand, despite relatively high level of the main drivers of innovation performance external to the firm in the Czech Republic, Slovakia and Hungary, their declining trend was noticed. This situation may result in a slowdown of competitiveness and European integration processes of the above countries. With regard to Poland, the results highlighted relatively very low of indicators related especially to attractive research systems and innovation-friendly environment dimensions. In that terms, Poland outstand the most from the group of the EU countries from V4. Such conditioning may influence negative to abilities to adaptation to uncertainty in the environment and rapid changes.

These findings have and policy practical implications. In this regard, the findings provide the necessity to improve actions enhancing the level of the main drivers of innovation performance external to the firm. Such actions should focus, among others, on shaping conditions for networking institutional environment, research organisations, universities and firms and may result in increasing competitiveness of the European Union and European integration processes.

This study is not without limitations. It would be interesting to investigate the causes of differences of the main drivers of innovation performance external to the firm between the Visegrad Group countries.

The complexity of the main drivers of innovation performance external to the firm requires further studies. In this respect, it seems necessary to investigate whether the results of the research also hold in other spatial contexts (regions). It would be also interesting to undertake similar studies applying multi-criteria statistical methods.

## **Abstract**

*The aim of the paper is to analyse how the nascence of firms which were subsidised in a transition economy with the EU funds is determined by the economic development. The EU funds and firms nascence in a transition economy were studied for Poland for 2007-2015 period. Hypotheses were tested with the usage of the Ordinary Least Squared regression with robust standard errors. The statistical significance of the results was determined with F-test. Data sources were the Statistics Poland and the final report of the Operational Programme Human Capital 2007-2013 Implementation in Poland. The main finding is that the nascence of subsidized firms in Poland, as well as the creation of new workplaces in these firms have not been determined by such dimensions as economy structure, innovative capacity, and entrepreneurial activity. The findings may be interesting for policymakers in establishing and implementing subsidy schemes for starting a business.*

**Keywords:** EU funds, nascent firms, Poland, subsidies, transition economy

**JEL Classification:** G18, L26, P25, R11

## **1. Introduction**

The importance of the financial sources for the firms establishment is uncontested, with capital constrains considered as a significant barrier of the nascence (e.g., Caliendo and Künn, 2014). Within different financial sources, the EU funds represent a substantial founding for newly born enterprises. Being directed to foster economic growth within the EU member states (Ederveen et al., 2006) such funds support inter alia starting a business, mostly by providing subsidies and concessional loans.

Start-up subsidies have been researched in a growing body of studies (e.g., Becker et al., 2010; Caliendo et al., 2015). However, this paper may contribute to the existing literature by focusing on a transition economy. With entrepreneurship being suppressed for decades of a centrally planned policy, such economy often suffers from low tendency for entrepreneurial activity. Particularly, it seems interesting to examine whether the economic environment does matter for the nascence of firms subsidized with the EU funds in a transition country. This issue has not been entirely recognised. Hence, the aim of the paper is to analyse how the nascence of these firms in Poland is determined by the economic development.

The paper contributes to the knowledge by considering whether the transformation environment impacts on a propensity for firm's nascence with the public subsidy. By regarding the significance of economic environment for the nascence of the subsidised firms this paper extends research on firm's performance in transition economies. The findings may be helpful in supporting entrepreneurial activity in these economies.

This paper is organized as follows. First section presents the theoretical background and problem formulation, while second section provides method of the research, together with data and variables description. Section three focuses on findings. This is followed by the conclusions.

## 2. Problem Formulation and Methodology

The EU funds impact on national and regional competitiveness (Melecký, 2016). With the subsidies for firm's nascence, the EU supports the increase of entrepreneurial activity. Specifically, these subsidies are aimed mainly in fostering unemployed persons to establish their own businesses. However, the overall impact of the EU funds may be heterogeneous. Some studies provide evidence that although these funds stimulate growth, their effect on employment increase is ambiguous (e.g., Becker et al., 2010). The subsidisation of the nascence of firms may also carry risk of dead-weight effect emergence. This effect appears when, with the aim of being subsidised, the nascent entrepreneurs record themselves as unemployed (Caliendo and Künn, 2014).

The nascence of firms is determined by the economic environment. The level of economic development is regarded as pivotal for self-employment dynamics (Wennekers et al., 2005). However, the dependence of firm's nascence on the economic development seems to be ambiguous. On the example of Germany, Caliendo and Künn found that good economic conditions weight for one sample of subsidised start-ups as against the other sample of such firms (2014). The possible explanation of this incoherence is seen in different features of firm founders (Caliendo and Künn, 2014). With the diversity (Maj, 2017), skills, experience, social networks, it seems that human capital does have a substantial influence on firms nascence.

Since human capital may influence attitudes towards entrepreneurial activity, it seems interesting to recognise the extent to which the level of this capital matters for a transition economy. With a scarcity of previous market competences (Smallbone and Welter, 2001), a transition economy often suffers from a deficit of skills necessary for establishing and running a business. However, it may be expected that along with transition processes, these skills adjust to a market economy (Zygmunt J., 2017). Entrepreneurial attitudes may be stimulated with the subsidies for start-ups. Hence, it is supposed that the influence of human capital on the nascence of firms is positive.

A transformation to a market economy involves a structural change from public owned manufacturing market (McMillan and Woodruff, 2002) to the increasing value of the service sector, which generally stimulates new business nascence (Wennekers et al., 2005). The sector of economic activity does also matter for start-ups survival rate (Geroski, 1995). It is anticipated then that the economy structure weights for decisions of establishing start-ups in a transition economy.

Economic development may be also embodied in innovative capacity. Inflows of knowledge seem to determine entrepreneurial activity (Acs et al., 2009), with R&D activities having an impact on the rate of innovation (Wennekers et al., 2005). Innovation is important for reaching the competitive advantages (Zygmunt A., 2017). With a knowledge transfer being mostly restricted in a centrally planned economy, the knowledge spillovers nearly do not occur. However, the transformation to a free market encourages R&D and innovation, and seems favourable for boosting entrepreneurial activity. Hence, it is expected that together with the growth of innovative capacity of a transition economy, the nascence of firms increases.

Hence, the following hypotheses are tested in this paper:

H1 Human capital in a transition economy supports the nascence of firms financed with the EU funds

H2 Economy structure of a transition country influences new firms establishment with public subsidies

H3 The nascence of firms with the support of the EU funds depends on innovative capacity of a transition economy

## 2.1 Model and Data

To research how the nascence of firms subsidised with the EU funds is determined by the economic development of a transition economy, the Ordinary Least Squared regression with robust standard errors was used. Hypotheses were tested with the following model:

$$NE(S)_i = \beta_0 + R\&D_i\beta_1 + I_i\beta_2 + ES_i\beta_3 + T_i\beta_4 + D_i\beta_5 + \varepsilon_i \quad (1)$$

F-test was employed to test for the model's statistical significance. To examine the regression's goodness-of-fit, the coefficient of determination ( $R^2$ ) was used. The autocorrelation was controlled with the Durbin-Watson statistic. High level of collinearity between variables was identified with Pearson's correlation. It was assumed that such collinearity is when Pearson's correlation coefficient is above 0.9.

The EU funds and the nascence of firms in a transition economy was studied on the example of Poland. Consistent with Ederveen et al. (2006) country-level approach was applied. Nonprobability sampling was used in terms of the research period. Since it seems important to regard the EU policy with its completed outcomes, the EU cohesion policy framework 2007-2013 was considered. Consequently, the research period is 2007-2015, allowing for the "n+2" financial rule<sup>1</sup>. However, since first outcomes of this policy were registered in 2008, data analysis starts from 2008 ( $i = 2008, 2009, \dots, 2015$ ).

With most of funds for firm's nascence coming in the regarded period from the Operational Programme Human Capital, the research attention was paid on the programme in question. The programme was covered by the European Social Fund (ESF) with more than 11.6 billion euro budget for Poland<sup>2</sup>, with 27% of this budget for professional qualifications rising and for firm's nascence. Average annual data were sourced from the Statistics Poland (Statistics Poland [online], 2018) and the Final Report of the Operational Programme Human Capital 2007-2013 Implementation in Poland (Sprawozdanie końcowe [online], 2017).

Dependent variable was a number of persons who received the EU funds for starting a business (per 10,000 inhabitants) in a year  $i$  ( $EN(S)_i$ ). Since the nascence of firm was a precondition for the EU funds appropriation, it was assumed that this number represents the firms established with the ESF as well. To check for robustness the analysis was also done for the whole population of nascent firms in the research period (model 2). This population was measured as the number of new firms per 10,000 inhabitants in a year  $i$  ( $EN_i$ ). The EU funds and firms nascence were also studied with  $WP(S)_i$  representing the number of new workplaces created within the ESF for starting a business per 10,000 inhabitants in a year  $i$  (model 3), with robustness check with  $WP_i$  referring to the number of new workplaces created in a year  $i$  per 10,000 inhabitants (model 4).

Explanatory variables were: inflows of knowledge in a year  $i$  ( $R\&D_i$ ), innovative activity in a year  $i$  ( $I_i$ ), human capital in a year  $i$  ( $T_i$ ), and economy structure in a year  $i$  ( $ES_i$ ). These variables were measured as follows:

- a.  $R\&D_i$  was proxy by the intramural R&D expenditure in PLN<sup>3</sup> per capita
- b.  $I_i$  was measured as spending in PLN on innovative activity in enterprises for one person who is professionally active
- c.  $T_i$  was measured as share of population with tertiary education degrees in relation to total employment (in %)
- d.  $ES_i$  was proxy by three variables to allow for all nature of economy structure. Hence, the agriculture sector ( $A_i$ ) was measured as share of employment in agriculture in total employment (in %). The industry sector ( $IN_i$ ) was measured as share of employment in industry in total employment (in %). The service sector ( $S_i$ ) was proxy by share of employment in service in total employment (in %).

It seems interesting to check for entrepreneurial activity in Poland. Hence, the control variable, population density ( $D_i$ ), was engaged. This approach is consistent with Wennekers et al. (2005) who argue that entrepreneurial activity is likely to increase along with the population density enhancement. It is expected that the number of nascent firm grows together with the increase of the population density.  $D_i$  was measured as the number of people per square kilometre.

Descriptive statistics of variables are shown in table 1.

**Table 1. Descriptive Statistics**

Variable	Mean	SD	Min	Max
<b>NE(S)</b>	8.07	2.98	3.12	12.59

Source: Own estimation based on: Statistics Poland [online], 2018; Sprawozdanie końcowe [online], 2017.

Because of high levels of collinearity which were identified between some variables, the following variables were excluded from the further consideration:  $A_i$ ,  $S_i$ ,  $T_i$ .

### 3. Problem Solution

The models' estimation results are shown in table 2. The findings for  $WP_i$  are not presented there since, with p-value for test F higher than 0.10, the model 4 proved to be statistically insignificant.

The results<sup>4</sup> indicate that innovative capacity does not impact the nascence of firms with the EU support. Inflows of knowledge and innovative activity in a transition economy seem to not weight in decisions of starting a business with a public subsidy. Similarly, the analysis for the number of new workplaces created in these firms has not revealed any statistically significant influence of innovative capacity. Hypothesis 2 has not been supported. However, the findings

for robustness check (Model 2) provide evidence that when the whole population of nascent firms is considered, the intramural R&D expenditure per capita is of consequence for starting a business.

**Table 2. Estimation Results**

Autocorrelation consistent. Level of statistical significance: \*\*\* $p \leq 0.01$ ; \*\*  $p \leq 0.05$ ; \* $p \leq 0.10$ . Source: Own estimation based on: Statistics Poland [online], 2018; Sprawozdanie końcowe [online], 2017

Contrary to research expectations, the relationship between the economy structure and the nascence of subsidized firms has not been identified. The economy structure has not also affected the number of new workplaces in firms established with the EU funds. It does not correspond to Hypothesis 3. Interestingly, the results for the whole population of new born firms lead to the conclusion of a great value of the economy structure for firm's nascence.

The analysis for the control variable does not reveal any significant impact of entrepreneurial activity both for starting a subsidized business and creating new workplaces there. The results for whole population of start-ups in Poland in the period 2007-2015 show albeit that population density influences the nascence of firms in a transition economy.

#### 4. Conclusion

This paper may contribute to the knowledge on entrepreneurship in transition economies by studying the nascence of firms subsidized with the EU funds, in reference to the economic environment. The following economic dimensions have been analysed: human capital, economy structure, innovative capacity, and entrepreneurial activity for Poland for the period 2007-2015. The findings provide evidence that firms nascence with the support of the EU funds, as well the creation of new workplaces in these firms have not been dependent on the economic environment. However, the analysis for the all new born firms in Poland in the research period allows to conclude of the substantial weight of inflows of knowledge, economy structure, and entrepreneurial activity in starting a business in a transition economy. With regard to this, the absence of the direct linkage between the economy development and the nascence of subsidized firms seems interesting and may indicate that the availability of a

subsidy predominately matters in decision for establishing such firm, compared with the other considerations. It may also reflect a moral hazard problem when generally lower requirements for such firms reduce the need to consider economic conditions that may affect the survival rates of these firms. This is to some extent in line with Caliendo et al. who proved that an incentive for subsidized firm's growth is diminished by the decreased requirements with regard to these firms outcomes (2015). The findings may be interesting for policymakers in establishing and implementing subsidy schemes for starting a business.

This paper suffers from some limitations. First, it does not control for the business cycle. Since this cycle relevantly influences the willingness for establishing a firm (e.g., Wennekers et al., 2005), it seems interesting in further research to identify to what extent the business cycle in a transition economy determines the nascence of firms financed with the public subsidy. Second, the possible interactions between these firms and the economy have not been regarded in this paper. More specifically, the impact of the nascence of these firms on economic development has not been considered. Third, some may argue that since this study regards the EU funds within ESF, which were oriented mostly on entrepreneurship development among persons who remain workless, a limitation of this study is that it focuses only on "necessity" entrepreneurs. However, this paper follows the approach of Shane who claims that regardless of motivation for starting a business, the firm track record may be similar (2009, p. 142). Nonetheless, some studies provide evidence that even if such firms face higher survival rates, they often are less effective in terms of innovation, growth, and income (Caliendo et al., 2015). With regard to that future research on performance and survival of firms which were subsidised in a transition economy seems highly interesting.

### **Abstract**

*This research paper aims to estimate the impact of the European Structural and Investment Funds (ESIF) on economic growth of the Czech Republic during the period 2004-2015 using panel data regression techniques. ESIF are instruments of European economic and social cohesion policies. The primary goal of these policies is to foster economic growth and convergence among the member states of the European Union through the reallocation of financial resources from ESIF. During 2004-2015, the Czech Republic was involved in three programming periods in which projects of an approximate value of 939 billion CZK were supported and implemented. In that period, the contribution from ESIF amounted to approximately 757 billion CZK while 182 billion CZK were allocated from national resources. Besides the standard panel data econometric techniques like pooled OLS or FE, a spatial panel data econometric method is employed to verify the robustness of the results. Evidence of this research shows a positive relationship between ESIF and economic growth of NUTS3 regions of the Czech Republic. Furthermore, the results also indicate economic convergence achieved among NUTS3 regions of the Czech Republic.*

**Keywords:** economic convergence, economic growth, ESIF, regression analysis

**JEL Classification:** C23, H54, O40, R11

### **1. Introduction**

ESIF are instruments of European economic and social cohesion policies with the aim to support the economic growth of EU member states and promote economic convergence among them. Although the Czech Republic was involved in three programming periods during 2004-2015, in which it received financial aid of 757 billion CZK on various projects, the impact evaluation of ESIF on economic growth of the Czech Republic has not been carried out yet. Therefore, this research paper aims to estimate the impact of ESIF on regional economic growth of the Czech Republic during the period 2004-2015. Based on panel data regression techniques applied to macroeconomic data of NUTS3 regions, the results show that ESIF has had a positive impact on regional economic growth. Moreover, the models indicate that economic convergence among Czech regions has been achieved.

The first pioneering studies and analysis evaluating the impact of EU funds were presented already in the 1990s. The very first research papers investigated questions related to ESIF by using basic econometric techniques. For instance Gaspar and Pereira (1992) and Fuente et al. (1995) examine the impact of structural funds (hereinafter SF) and cohesion policy in EU countries like Spain or Portugal. Dall'èrba and Galo (2003) and Cappelen et al. (2003) investigated the impact of SF in terms of convergence among individual regions. These and

many other early studies confirmed the significant positive impact of SF on economic performance of EU countries and the convergence dynamics. Later on, the simple econometric techniques were replaced by more profound analyses that focused, among other, on spill-over effects stemming from the EU funds. Mohl and Hagen (2010) applied the spatial panel data regression model that accounts for spill-over effects to evaluate the impact of the EU funds in the programming period 2000-2006 using the data set covering NUTS2 territorial units. There is also a stream of literature that studies the effects of existing macroeconomic conditions and institutional or political environment on effectiveness of the EU funds (e.g. Cappelen et al. 2003, or Kulhanek 2014). Some other studies, such as Pellegrini et al. (2013) or Maynou et al. (2014), confirmed the positive impact of SF on economic growth with moderate effects on the convergence among regions using the data covering the programming period 2007-2013.

In the Czech Republic, there is a minority of studies employing quantitative or modelling approaches aimed at impact evaluation of the EU funds. The latest examples of such studies are Kejak and Vávra (1999) and Ministry of Regional Development (2006). The former paper utilises the HERMIN model to estimate potential impacts of the EU funds on the macroeconomic conditions in the Czech Republic through expenditures on physical infrastructure during the programming period 2000-2006. The later MMR's paper employs the same model for the ex-ante impact evaluation of the programming period 2007-2013 on macroeconomic situation in the Czech Republic. There is thus still potential for further research.

The rest of the paper is organised as follows. Section 2 outlines the methodology. Section 3 discusses the estimation of results. Section 4 concludes.

## 2. Methodology

### 2.1 Model Specification

To evaluate the impact of ESIF on the regional economic growth of the Czech Republic a neoclassical growth model has been used. The modelling approach closely follows Rodríguez-Pose and Novak (2013). The variables are specified in lags due to potential endogeneity which might bias the estimates of parameters, and therefore negatively affect the results of the estimation. The baseline model to be estimated takes the following form:

$$\ln(y_{i,t}/y_{i,t-1}) = \beta_0 + \beta_1 \ln(y_{i,t-1}) + \beta_2 \ln(innov_{i,t-1}) + \beta_3 \ln(ESIF_{i,t-1}) + \beta_4 infr_{i,t-1} + \beta_5 educ_{i,t-1} + u_{i,t} \quad (1)$$

where the subscript  $i = 1, \dots, 14$  denotes the region and the subscript  $t = 1, \dots, 12$  denotes the time period.  $y_{i,t}$  is the real GDP per capita,  $innov_{i,t}$  measures R&D activity,  $ESIF_{i,t}$  is the variable capturing the ESIF,  $infr_{i,t}$  stands for the level of infrastructure, and  $educ_{i,t}$  is an indicator of a quality of human capital. The reasoning to include individual variables is following.

- Real GDP per capita ( $y_{i,t}$ ): A standard measure of regional economic performance. Its lagged value captures the conditional convergence and the starting growth position.
- Research and development ( $innov_{i,t}$ ): Innovation has long been recognized as a key factor for sustainable economic growth. In particular, Křístková (2012) and Křístková (2013) find a positive impact of R&D activities on economic growth in the Czech Republic. Literature identifies several possible explanatory variables for R&D. Due

to limited data availability at the regional level, private R&D expenditures, public R&D expenditures, or number of patents are available. Since the patent activity in the Czech Republic is not so high and public R&D expenditures might serve different purposes than innovation activities, private R&D expenditures are seen as the most suitable candidate. Private R&D expenditures are expressed in per capita terms.

- The level of infrastructure ( $infr_{i,t}$ ): A number of studies have confirmed the significant impact of infrastructure on economic growth (e.g. Aschauer 1989, Canning 1999, Demetriades and Mamuneas 2000, or Röller and Waverman 2001). Therefore, infrastructure development is seen as an important factor behind economic growth. Various studies use various proxies for infrastructure (such as motorways, railways, or telecommunications). In order to obtain more complex and robust indicator of infrastructure development, the approach of Calderon and Servén (2004) (who construct the composite index of infrastructure based on principal component analysis) is employed. The index includes three variables: the density of the road network per square km, the density of railway lines per square km and the installed power capacity per one thousand inhabitants.
- The quality of human capital ( $educ_{i,t}$ ): Standard growth regressions account for human capital as one of the main drivers of economic growth (e.g. Oancea et al. (2017) find a positive relationship for the Czech Republic). The common approach is to use a share of population with tertiary education as a proxy variable.

During the investigated period the Czech Republic experienced a significant drop in economic growth caused by the financial crisis. This situation led to a suspicion about an existence of a structural break. As the time of this structural break is known, the data sample has been divided into two subsamples (2004-2008 and 2009-2015). A statistical significance of this break has been investigated by using of the Chow test of a structural change. The statistical test confirms the presence of the structural break (10.16, p-value: 0.000). The baseline model (1) is augmented with the dummy variable  $sb_{i,t}$  to control for this issue:

$$\ln(y_{i,t}/y_{i,t-1}) = \beta_0 + \beta_1 \ln(y_{i,t-1}) + \beta_2 \ln(innov_{i,t-1}) + \beta_3 \ln(ESIF_{i,t-1}) + \beta_4 infr_{i,t-1} + \beta_5 educ_{i,t-1} + \beta_6 sb_{i,t} + u_{i,t} \quad (2)$$

The results of the applied panel data regression methods on the model (2) might be biased due to spatial effects. As the interconnection between the regions is substantial, the economic performance of one region can significantly affect the economic performance of its neighbouring regions. To account for the spill-over effects, the spatial panel data regression method (the spatial lag model) in line with Elhorst (2009) is employed. The spatial lag model relies on the weighting matrix  $W$  that contains information about the interconnection between the regions. The matrix  $W$  is square and symmetric, and it has fourteen rows (columns) that correspond to fourteen regions that constitute the Czech Republic. The diagonal elements of the matrix  $W$  are equal to zero and the non-diagonal entries  $w_{jk}$  characterize the spatial dependence between the region  $j$  and  $k$ . Following Ertur and Koch (2006), the weighting matrix is constructed based on geographical distance between the capitals of the regions (because the capital of region Praha and Středočeský kraj coincide, distance between these two regions is set arbitrarily to 20 km). The matrix is normalised such that the sum of elements across the rows is equal to one. The elements of the weighting matrix  $W$  are defined as  $w_{jk} = w_{jk}^* / \sum_j w_{jk}^*$  with:

$$w_{jk}^* = \begin{cases} 0 & \text{if } j=k \\ d_{jk}^{-2} & \text{otherwise} \end{cases}$$

where  $d_{jk}$  is distance between capitals of the region  $j$  and  $k$ . To capture the gravity function, the second power of distance is utilised. Apart from the inclusion of the spatially weighted dependent variable, the model (2) remains unchanged. Therefore, the spatial lag model takes the form:

$$\ln(y_{i,t}/y_{i,t-1}) = \beta_0 + \rho W \ln(y_{i,t}/y_{i,t-1}) + \beta_1 \ln(y_{i,t-1}) + \beta_2 \ln(\text{innov}_{i,t-1}) + \beta_3 \ln(\text{ESIF}_{i,t-1}) + \beta_4 \ln \text{fr}_{i,t-1} + \beta_5 \text{educ}_{i,t-1} + \beta_6 \text{sb}_{i,t} + u_{i,t} \quad (3)$$

Since the model specified in equations (1) to (3) contains a dynamic component, it is possible to compute the long-term impact of ESIF on economic growth (please see Mohl and Hagen (2010) for the derivation of the long-term elasticity). The long-term impact is then interpreted as elasticity, i.e., a one percent increase of ESIF per capita leads to an increase in the regional real GDP per capita by X percent.

## 2.2 Data

The dataset contains data for fourteen NUTS3 regions of the Czech Republic. The data sample covers the period 2004-2015 on a yearly basis. In total, the data sample creates a balanced panel with 168 observations. The primary data sources are the monitoring systems MSSF, MSC2007 and MSC2014+ of the Ministry of Regional Development of the Czech Republic, an open source database of the Czech Statistical Office and ARAD database of the Czech National Bank.

**Table 1: Descriptive Statistics (overall)**

Variable	Mean	SD	Min	Max	Observations
Real GDP p.c. growth	0.021	0.036	-0.089	0.104	168
Ln real GDP p.c.	12.716	0.259	12.441	13.664	168
Ln private expenditures on R&D p.c.	7.449	0.819	4.986	9.035	168
Ln ESIF payments p.c.	8.030	1.898	1.267	10.171	168
Index of infrastructure	-1.145	0.747	-2.555	0.210	168
Number of people with tertiary education, a share of population	0.093	0.039	0.041	0.242	168

**Table 2: Correlations**

Variable	(a)	(b)	(c)	(d)	(e)	(f)
Real GDP p.c. growth (a)	1.000					
Ln real GDP p.c. (b)	0.023	1.000				
Ln private expenditures on R&D p.c. (c)	0.059	0.632	1.000			
Ln ESIF payments p.c. (d)	-0.393	0.131	0.144	1.000		
Index of infrastructure (e)	-0.109	-0.508	-0.536	0.149	1.000	
Number of people with tertiary education, a share of population (f)	-0.064	0.883	0.707	0.306	-0.486	1.000

The financial sources from ESIF funds comprise the financial sources implanted under the National strategic reference framework for the first two programming periods (2004-2013) and

the Partnership agreement for the last programming period (2014-2015). Additionally, the data from Rural Development Program were employed. The dataset contains only the payments that can be addressed to individual regions, i.e., multi-regional programmes are not included. The database of the Czech Statistical Office is used to retrieve data on regional GDP per capita, private expenditures on R&D activities, tertiary education and infrastructure. The GDP deflator is obtained from ARAD database. An open source website tool ([www.vzdalenostmest.cz](http://www.vzdalenostmest.cz)) is used to compute distances between the capitals of the regions. The descriptive statistics of data is offered by table 1. Table 2 summarises correlations between the variables.

### 3. Estimations and results

#### 3.1 “Standard” Panel Regressions

The estimation procedure follows Mohl and Hagen (2010). First, the model (2) is estimated using the pooled OLS estimator. Then, the fixed effects model is chosen as superior to pooled OLS and random effects model based on the F test (5.23, p-value: 0.000) and the Hausman test (260.31, p-value: 0.000). Since the Wooldridge test of first-order autocorrelation (Wooldridge, 2002) suggests its presence, clustered standard errors are employed to control for serial correlation. Lastly, the method proposed by Driscoll and Kraay (1998) is applied to adjust standard errors for heteroskedasticity, serial correlation and spatial correlation. The results of individual stages of the fixed effects model estimation are summarised in tables 3.

**Table 3: Results of the Fixed Effects Models**

	(I)	(II)	(III)
Variables	Fixed effects (robust SE)	Fixed effects (clustered SE)	Fixed effects (Driscoll- Kraay SE)
$\ln(y_{i,t-1})$	-0.5825*** (0.0640)	-0.5825*** (0.0683)	-0.5825*** (0.1436)
$\ln(\text{innov}_{i,t-1})$	0.0231** (0.0104)	0.0231 (0.0134)	0.0231* (0.0105)
$\ln(\text{ESIF}_{i,t-1})$	0.0094*** (0.0026)	0.0094*** (0.0031)	0.0094* (0.0043)
$\text{infr}_{i,t-1}$	0.0413** (0.0178)	0.0413 (0.0273)	0.0413** (0.0174)
$\text{educ}_{i,t-1}$	0.5422*** (0.2059)	0.5422* (0.2935)	0.5422 (0.3680)
$\text{sb}_{i,t}$	-0.0529*** (0.0076)	-0.0529*** (0.0077)	-0.0529*** (0.0084)
constant	7.1659*** (0.7824)	7.1659*** (0.8082)	7.1659*** (1.7778)
Long-term elasticity	0.0161	0.0161	0.0161
R-squared	0.586	0.586	0.586

Note: \*\*\* p<0.01, \*\* p<0.05, \* p<0.1

Independently of the estimation procedure, the initial level of GDP per capita is negative and highly statistically significant. This result suggests a presence of the conditional convergence

among regions of the Czech Republic. In other words, the less developed regions catch up with more developed ones. Despite the shorter length of the time series (12 years), the model suggests clear evidence of this process. Nevertheless, the strong conclusion about the long-term convergence process cannot be made. The innovation variable is estimated with a positive impact and in estimations (I) and (III) is significant. The same holds for the variable characterising the level of infrastructure in the regions. The variable capturing the level of human capital is positively related to the regional growth of GDP; however, in the last estimation method (III) it is highly insignificant. The prominent variable of interest (the financial sources from the ESIF) is positive and significant throughout the estimations (I) to (III). The short-term elasticity is estimated to be 0.0094, while the long-term elasticity is equal to 0.0161 suggesting that one percent increase in financial funds from the ESIF per capita increases regional real GDP per capita by 0.9% and 1.6% respectively. The results related to the ESIF are quantitatively similar to those of Mohl and Hagen (2010).

### **3.2 Spatial Panel Regression**

The results reported in the previous subsection (except for the Driscoll-Kraay method) might be biased due to the spatial correlation that is expected to be present. To put it simply, the economic performance of one region can significantly affect the economic performance of its neighbours. The spatial panel data regression method is applied to account for the spill-over effects among the regions.

The estimation of equation (3) begins again with statistical tests aimed to clarify whether the fixed effects or random effects should be employed. The null hypothesis under the Hausman test is rejected (48.32, p-value: 0.000) suggesting that the fixed effects model should be used. Moreover, standard errors are corrected for heteroskedasticity and serial correlation. The results of spatial panel fixed effects regressions are summarised in table 4. The indicator that tests the presence of spatial spill-over effects is given by the significance of the coefficient  $\rho$  of the weighting matrix  $W$ . The coefficient  $\rho$  is positive and highly significant in all cases. Moreover, compared to the results of the previous regressions, the values of the coefficients of the explanatory variables are reduced. This suggests that a certain portion of the explanatory power of variables was caused by spill-over effects.

**Table 4: Results of the Spatial Panel Lagged Model**

	(I)	(II)	(III)
Variables	SAR fixed effects	SAR fixed effects (robust SE)	SAR fixed effects (Driscoll- Kraay)
$\ln(y_{i,t-1})$	-0.4144*** (0.0559)	-0.4144*** (0.0650)	-0.4144*** (0.0742)
$\ln(innov_{i,t-1})$	0.0015* (0.0083)	0.0015 (0.0116)	0.0015 (0.00061)
$\ln(ESIF_{i,t-1})$	0.0069*** (0.0021)	0.0069** (0.0027)	0.0069** (0.0022)
$infr_{i,t-1}$	0.0291** (0.0142)	0.0291* (0.0170)	0.0291* (0.0125)
$educ_{i,t-1}$	0.1909 (0.1705)	0.1909 (0.2160)	0.1909 (0.1951)
$sb_{i,t}$	-0.0260*** (0.0071)	-0.0260*** (0.00852)	-0.0260*** (0.0037)
$\rho$	0.4537*** (0.0631)	0.4537*** (0.0421)	0.4537*** (0.0428)
Long-term elasticity	0.0167	0.0167	0.0167
R-squared	0.6023	0.6023	0.6023

Note: \*\*\* p<0.01, \*\* p<0.05, \* p<0.1

The signs of all the coefficients are the same as in the “standard” regressions. There is a negative highly significant impact of the initial real GDP per capita. Innovation and the level of infrastructure bring a significant positive impact on the GDP growth rate. A positive effect is attributed to the level of education; however, it is highly insignificant. Based on the spatial lag model estimation, an increase of one percent in financial funds from the ESIF per capita increases regional real GDP per capita by 0.69% on average keeping the other variables constant. The long-term elasticity indicates even a higher impact of 1.7%.

#### 4. Conclusion

Although the use of quantitative methods aimed at the impact assessment of the EU funds is a commonly used approach abroad, there are few such analyses in the Czech Republic. For that reason, the paper contributes to the current Czech literature by (i) investigating the impact of ESIF on economic growth of Czech regions using quantitative modelling approaches and (ii) applying dynamic panel data regression techniques that control for spatial effects. In particular, this paper reveals that the projects co-financed from ESIF for approximately 939 billion CZK in period 2004-2015 do have a positive effect on economic growth of regions of the Czech Republic. Based on the model estimations, a one percent increase of payments from the ESIF per capita leads to a positive impact on the regional GDP per capita between 0.69% and 0.94%. The long-term effects are even stronger, 1.6% to 1.7%. The results also indicate strong regional spill-over effects that have a significant positive impact on the economic performance of regions. Apart from the effects of ESIF, the regression analyses bring evidence of the significant positive impact of innovation and research activities on economic growth. There is also a positive impact of infrastructure development on regional growth in the Czech Republic.

Moreover, the model shows that there is a positive economic convergence among the regions of the Czech Republic.
